Abstract

Berkeley Cardinals and the search for $V$

Raffaella Cutolo

This thesis is concerned with Berkeley cardinals, very large cardinal axioms inconsistent with the Axiom of Choice. These notions have been recently introduced by J. Bagaria, P. Koellner and W. H. Woodin; our aim is to provide an introductory account of their features and of the motivations for investigating their consequences. As a noteworthy advance in the topic, we establish the independence from ZF of the cofinality of the least Berkeley cardinal, which is indeed the main point to focus on when dealing with the failure of Choice. We then explore the structural properties of the inner model $L(V_{\delta+1})$ under the assumption that $\delta$ is a singular limit of Berkeley cardinals each of which is a limit of extendible cardinals, lifting some of the theory of the axiom $I_0$ to the level of Berkeley cardinals. Finally, we discuss the role of Berkeley cardinals within the ultimate project of attaining a “definitive” description of the universe of set theory.

Acknowledgements

I would like to thank Peter Koellner and Hugh Woodin, for sharing with me their research and their brilliant ideas, and for serving as advisors of this thesis.

I would also like to thank Alessandro Andretta, for his precious suggestions and teachings, and for giving me the opportunity of an outstanding experience, which led to realize this work.
Chapter 1

Introduction

Have you ever asked how far the mathematical infinite goes?

Providing the answer to this question is a primary challenge of set theory: it involves, on the one hand, large cardinal axioms (positing the existence of higher and higher infinities), and, on the other, set-theoretic principles limiting the extent of infinity that can (consistently) be demanded to exist; remarkably, on top of these principles we encounter the Axiom of Choice, for it readily implies that Reinhardt cardinals are inconsistent, and this settles the above question in the context of ZFC. But what if we work in just ZF? For all we know, the large cardinal hierarchy could then extend far beyond . . .

It is indeed an open problem whether it is consistent with ZF that there exists a Reinhardt cardinal, i.e., the statement that there is a non-trivial elementary embedding of the universe $V$ into itself. This assertion arises as the limit case within a general template for the formulation of very large cardinal axioms (namely, by the level of measurable cardinals onward), according to which the large cardinal is just the critical point of a non-trivial elementary embedding $j : V \rightarrow M$, where $M$ is a transitive class and the critical point of $j$ is the least ordinal moved (upwardly) by $j$, and the higher the degree of resemblance required between $M$ and $V$ (i.e., the extent of closure satisfied by $M$), the
stronger the large cardinal property holding at \( \text{crit}(j) \). The axiom demanding full resemblance between \( M \) and \( V \) (that is, \( M = V \)) was proposed by Reinhardt; shortly after its introduction, it was ruled out by Kunen, showing that if \( j : V \to M \) is a non-trivial elementary embedding and \( \lambda \) is the supremum of the critical sequence of \( j \) then \( j^\lambda \notin M \), and hence \( M \neq V \). In other words, for any non-trivial \( j : V \to M \), the pointwise image of \( \lambda \) is not in \( M \) where \( \lambda \) is the least ordinal above \( \text{crit}(j) \) such that \( j(\lambda) = \lambda \). However, the proof of Kunen’s theorem makes an essential use of the Axiom of Choice (the original version as well as all subsequent proofs known so far), and so, it actually tells us that “there are no Reinhardt cardinals as long as we work in ZFC”.

It is worth to mentioning the following corollary of Kunen’s proof, which is indeed a stronger version of his theorem: for any ordinal \( \delta \) there is no non-trivial elementary embedding \( j : V_{\delta+2} \to V_{\delta+2} \). Thus, the interest in studying large cardinals lying just below the Kunen inconsistency invites us to consider the following axiom, known as \( I_0 \): we say that \( I_0 \) holds at \( \lambda \) if there exists an elementary embedding \( j : L(V_{\lambda+1}) \to L(V_{\lambda+1}) \) such that \( \text{crit}(j) < \lambda \); it follows immediately that \( \lambda \) equals the supremum of the critical sequence of \( j \), call it \( \lambda' \), as if \( \lambda > \lambda' \) then \( j \upharpoonright V_{\lambda'+2} : V_{\lambda'+2} \to V_{\lambda'+2} \) is non-trivial, contradicting the local version of Kunen’s theorem. \( I_0 \) was introduced by Woodin, and to assume that \( I_0 \) holds at \( \lambda \) provides the inner model \( L(V_{\lambda+1}) \) with a rich structure theory, revealing deep analogies with the theory of \( L(\mathbb{R}) \) (which is just \( L(V_{\omega+1}) \)) under the assumption that the Axiom of Determinacy holds in \( L(\mathbb{R}) \); as an example of similarity with \( L(\mathbb{R}) \), we have that under \( I_0 \), \( L(V_{\lambda+1}) \) does not satisfy the Axiom of Choice. Other remarkable similarities between \( L(V_{\lambda+1}) \) and \( L(\mathbb{R}) \) (under the respective cited axioms) concern the Coding Lemma and the existence of measurable cardinals: in particular, the measurability of \( \lambda^+ \) (respectively,
1.1 Preliminary remarks

Our base theory is ZF (Zermelo-Fraenkel set theory).

We denote by $V$ the universe of set theory, i.e., $\bigcup \alpha V_\alpha$, where the sets $V_\alpha$ are defined by transfinite recursion, starting by the empty set and iterating the power set operation $\mathcal{P}$:

\[ \omega_1 \text{ and the properties of the ordinal } \Theta,^1 \text{ such as the fact that } \Theta \text{ is limit of measurables and for all } \alpha < \Theta, \mathcal{P}(\alpha) \in L_\Theta(V_{\lambda+1}) \text{ (respectively, } L_\Theta(\mathbb{R})). \]

Returning to our preliminary question: since the limitative result of Kunen doesn’t apply to the context of ZF, if we put aside the Axiom of Choice then it makes sense to look at the possibility that Reinhardt cardinals exist; and in fact, we will examine the case that the large cardinal hierarchy encompasses them and proceeds upward, through even stronger hypotheses (actually the strongest formulated so far) that we will call “Berkeley cardinals”. Rather surprisingly, these very large cardinal axioms will enable us to lift the main results of the $I_0$ theory to a higher level, offering a potential new candidate for the comparison with models of determinacy. Does this provide evidence for their consistency? At this stage, the real point turns out to be the following: these strong axioms of infinity are probably inconsistent with ZF, in that they seem to yield “too much power”, and establishing such an inconsistency would be a first (and crucial) step toward a sharper indication on where the large cardinal hierarchy definitely breaks down. Nevertheless, at the present time, it still remains possible that Berkeley cardinals may legitimately exist in ZF. Ultimately, as we shall see, the first of the two cases would bring us very close to determining the final picture of the universe $V$.

---

^1In the respective cases, $\Theta$ is equal to $\sup\{\alpha : \exists \pi : V_{\lambda+1} \xrightarrow{onto} \alpha \ (\pi \in L(V_{\lambda+1}))\}$ and $\sup\{\alpha : \exists \pi : \mathbb{R} \xrightarrow{onto} \alpha \ (\pi \in L(\mathbb{R}))\}$. 

3
1.1. PRELIMINARY REMARKS

- \( V_0 = \emptyset \);
- for any ordinal \( \alpha \), \( V_{\alpha+1} = \mathcal{P}(V_{\alpha}) \);
- for \( \lambda \) limit, \( V_\lambda = \bigcup_{\alpha < \lambda} V_{\alpha} \).

Recall that for every ordinal \( \alpha \), \( V_\alpha = \{ x : \text{rank}(x) < \alpha \} \), where \( \text{rank}(x) \) is the least ordinal \( \beta \) such that \( x \in V_{\beta+1} \).

A set \( a \) is **ordinal definable** if it is definable from some finite sequence of ordinals, i.e., there exist a formula \( \varphi(x, y_1, \ldots, y_n) \) of the language of set theory and ordinals \( \alpha_1, \ldots, \alpha_n \) such that \( \{ a \} = \{ x : \varphi(x, \alpha_1, \ldots, \alpha_n) \} \). OD is the class of ordinal definable sets. A set \( a \) is **hereditarily ordinal definable** if \( a \) is ordinal definable and its transitive closure is contained in OD (i.e., all members of \( a \), members of members of \( a \), and etc., are in OD). HOD is the class of hereditarily ordinal definable sets; it is provable in ZF that HOD satisfies ZFC (Zermelo-Fraenkel set theory with the Axiom of Choice).

The **constructible universe** \( L = \bigcup \alpha L_\alpha \) is the smallest inner model of ZF; the sets \( L_\alpha \) are defined by transfinite recursion, starting by the empty set and taking at any step \( \alpha + 1 \) just the definable subsets of the set of level \( \alpha \):

- \( L_0 = \emptyset \);
- for any ordinal \( \alpha \), \( L_{\alpha+1} = \text{def}(L_\alpha) \) is the set of all subsets of \( L_\alpha \) which are definable with parameters over \( (L_\alpha, \in) \);
- for \( \lambda \) limit, \( L_\lambda = \bigcup_{\alpha < \lambda} L_\alpha \).

\( L \) was introduced by Gödel in his proof of consistency of the Axiom of Choice. In fact, \( L \models \text{ZFC} \).

For any set \( A \), the **constructible closure** \( L(A) = \bigcup \alpha L_\alpha(A) \) is the smallest inner model of ZF that contains \( A \) as a member, with \( L_\alpha(A) \) defined as follows:
1.1. PRELIMINARY REMARKS

- $L_0(A) = \text{tr cl} \{A\}$ is the transitive closure of $\{A\}$;
- for any ordinal $\alpha$, $L_{\alpha+1}(A) = \text{def}(L_\alpha(A))$ is the set of all subsets of $L_\alpha(A)$ which are definable with parameters over $(L_\alpha(A), \in)$;
- for $\lambda$ limit, $L_\lambda(A) = \bigcup_{\alpha<\lambda} L_\alpha(A)$.

Unless $\text{tr cl} \{A\}$ has a well-ordering in $L(A)$, $L(A)$ does not satisfy the Axiom of Choice.

For $M$ and $N$ transitive models of a fragment of ZF, $j : M \rightarrow N$ is an elementary embedding iff for all formulas $\varphi(x_1, \ldots, x_n)$ of the language of set theory and for all $a_1, \ldots, a_n \in M$,

$$M \models \varphi(a_1, \ldots, a_n) \iff N \models \varphi(j(a_1), \ldots, j(a_n)).$$

If $j$ is the identity map on $M$, then $M$ is an elementary substructure of $N$, denoted $M \prec N$. We say that $j$ is non-trivial if $j$ is not the identity on the ordinals; then, the critical point of $j$ (abbreviated $\text{crit}(j)$) is the least ordinal $\alpha$ such that $j(\alpha) > \alpha$. 
Chapter 2

The Choiceless Hierarchy

In this chapter we describe the hierarchy of large cardinals incompatible with the Axiom of Choice. We define Berkeley cardinals, a notion introduced in [1], and establish some relative consistency implications between them and the other “choiceless” large cardinals presented. We conclude by providing the proof that the failure of the Axiom of Choice is essentially related with the cofinality of the least Berkeley cardinal, whose determination turns out to be the key point of interest. The content of this chapter follows [1] very closely and is included in order to make the thesis self-contained.

2.1 From Reinhardt Cardinals upward

We start by defining the hierarchy of Reinhardt cardinals and by mentioning the fundamental result established by Kunen, showing they are inconsistent in ZFC (for the proof of Kunen’s theorem see [3] ch.5).

Definition 2.1.1 (NBG\(^1\)). A cardinal \(\kappa\) is Reinhardt if there exists a non-trivial elementary embedding \(j : V \to V\) such that \(\text{crit}(j) = \kappa\).

\(^1\)Von Neumann-Bernays-Gödel set theory (without the Axiom of Choice), a conservative extension of ZF.
2.1. FROM REINHARDT CARDINALS UPWARD

**Theorem 2.1.2 (ZFC). (Kunen’s Theorem)** There is no non-trivial elementary embedding $j : V \to V$, i.e., there are no Reinhardt cardinals.

**Open Question.** Is it consistent with ZF that there exists a Reinhardt cardinal? In other words, can there be a non-trivial elementary embedding $j : V \to V$ in the context of ZF?

Throughout this dissertation we work in ZF; in this context, the notion of being a strongly inaccessible cardinal is reformulated as follows:

**Definition 2.1.3 (ZF).** A cardinal $\kappa$ is strongly inaccessible if for all $\alpha < \kappa$ there is no cofinal map $\rho : V_\alpha \to \kappa$.

**Remark 2.1.4.** Recall that:

1. If $\kappa$ is strongly inaccessible then $V_\kappa \models ZF$.
2. $(V_\kappa, V_{\kappa+1}) \models ZF_2$ if and only if $\kappa$ is strongly inaccessible.
3. If $\kappa$ is Reinhardt then $\kappa$ is strongly inaccessible; moreover, $\kappa$ is a limit of strongly inaccessible cardinals.

**Definition 2.1.5 (NBG).** A cardinal $\kappa$ is super Reinhardt if for all ordinals $\lambda$ there exists a non-trivial elementary embedding $j : V \to V$ such that $\text{crit}(j) = \kappa$ and $j(\kappa) > \lambda$.

It is not known whether the assumption that $\kappa$ is a super Reinhardt cardinal implies that there exists a Reinhardt cardinal below $\kappa$; however, a super Reinhardt rank-reflects a Reinhardt cardinal:

**Theorem 2.1.6.** Suppose $\kappa$ is a super Reinhardt cardinal. Then there exists $\gamma < \kappa$ such that $(V_\gamma, V_{\gamma+1}) \models ZF_2 + \text{"There exists a Reinhardt cardinal"}$.

\footnote{Second-order version of ZF in the context of full second-order logic, where the second-order quantifiers range over $\mathcal{P}(V_\kappa) = V_{\kappa+1}$.}
Proof. Let \( j : V \to V \) be a non-trivial elementary embedding with \( \text{crit}(j) = \kappa \). Let \( \langle \kappa_i : i < \omega \rangle \) be the critical sequence of \( j \), defined by \( \kappa_0 = \kappa \), \( \kappa_{i+1} = j(\kappa_i) \) for all \( i < \omega \). Let \( \lambda = \sup \{ \kappa_i : i < \omega \} \). Notice that \( \lambda \) is fixed by \( j \), as \( j(\lambda) = j(\sup \{ \kappa_i : i < \omega \}) = \sup \{ j(\kappa_i) : i < \omega \} = \sup \{ \kappa_{i+1} : i < \omega \} = \sup \{ \kappa_i : i < \omega \} = \lambda \). By assumption, there exists a non-trivial elementary embedding \( j' : V \to V \) such that \( \text{crit}(j') = \kappa \) and \( j'(\kappa) > \lambda \). Since \( \kappa \) is a limit of strongly inaccessible cardinals, by elementarity, \( j'(\kappa) \) is a limit of strongly inaccessible cardinals. Let \( \gamma_0 \) be the least strongly inaccessible cardinal greater than \( \lambda \). Since \( \gamma_0 \) is definable from \( \lambda \) and \( j(\lambda) = \lambda \), we have that \( j(\gamma_0) = \gamma_0 \); therefore, \( j \upharpoonright V_{\gamma_0} : V_{\gamma_0} \to V_{\gamma_0} \) is an elementary embedding with critical point \( \kappa \), witnessing that \( (V_{\gamma_0}, V_{\gamma_0+1}) \models \text{ZF}_2 + "\kappa \text{ is Reinhardt}". \) Thus, since \( \gamma_0 < j'(\kappa) \), by applying \( j'^{-1} \) we get that there exists \( \gamma = j'^{-1}(\gamma_0) < \kappa \) such that \( (V_\gamma, V_{\gamma+1}) \models \text{ZF}_2 + "\text{There exists a Reinhardt cardinal}". \)

Definition 2.1.7 (NBG). Suppose \( A \) is a proper class. A cardinal \( \kappa \) is \textbf{\( A \)-Reinhardt} if there exists a non-trivial elementary embedding \( j : V \to V \) such that \( \text{crit}(j) = \kappa \) and \( j(A) = A \). A cardinal \( \kappa \) is \textbf{\( A \)-super Reinhardt} if for all ordinals \( \lambda \) there exists a non-trivial elementary embedding \( j : V \to V \) such that \( \text{crit}(j) = \kappa \), \( j(\kappa) > \lambda \) and \( j(A) = A \) (where \( j(A) = \bigcup \alpha j(A \cap V_\alpha) \)).

Definition 2.1.8. Suppose \( \kappa \) is a strongly inaccessible cardinal. Then \( \kappa \) is \textbf{totally Reinhardt} if for each \( A \in V_{\kappa+1} \), \( (V_\kappa, V_{\kappa+1}) \models "\text{There exists an} \ A \text{-super Reinhardt cardinal}". \)

By definition, if \( \kappa \) is a totally Reinhardt cardinal then \( \kappa \) reflects a super Reinhardt cardinal (i.e., \( (V_\kappa, V_{\kappa+1}) \models \text{ZF}_2 + "\text{There exists a super Reinhardt cardinal}" \)); it is an open question whether a totally Reinhardt cardinal rank-reflects a super Reinhardt.

We now introduce the Berkeley hierarchy.
Definition 2.1.9. For any transitive set $M$, let $\mathcal{E}(M)$ be the collection of all non-trivial elementary embeddings $j : M \rightarrow M$.

Definition 2.1.10. An ordinal $\delta$ is a **proto-Berkeley cardinal** if for all transitive sets $M$ such that $\delta \in M$ there exists $j \in \mathcal{E}(M)$ with $\text{crit}(j) < \delta$.

Remark 2.1.11. Notice that:

1. If $\delta$ is a proto-Berkeley cardinal then, in particular, for any $\lambda > \delta$ there exists a non-trivial elementary embedding $j : V_\lambda \rightarrow V_\lambda$ with $\text{crit}(j) < \delta$.

2. If $\delta_0$ is the least proto-Berkeley cardinal then every ordinal $\delta$ greater than $\delta_0$ is also a proto-Berkeley cardinal.

It turns out that in the context of Berkeley cardinals we have elementary embeddings fixing any given set; this very powerful feature is a consequence of the following lemma.

Lemma 2.1.12. For any set $a$ there exists a transitive set $M$ such that $a \in M$ and $a$ is definable (without parameters) in $M$.

Proof. Let $\lambda$ be a limit ordinal such that $a \in V_\lambda$, and let $M = V_\lambda \cup \{\langle a, x \rangle : x \in V_\lambda\}$. Then, $M$ is a transitive set and $a$ is definable (without parameters) in $M$ as the first element in the pairs belonging to the set of highest rank. \hfill \Box

Corollary 2.1.13. Suppose $\delta$ is a proto-Berkeley cardinal. Then for every set $a$ there exists a transitive set $M$ and a $j \in \mathcal{E}(M)$ such that $\text{crit}(j) < \delta$ and $j(a) = a$.

Proof. By Lemma 2.1.12, there exists a transitive set $M$ such that $a \in M$ and $a$ is definable (without parameters) in $M$. We can choose $M$ such that $\delta \in M$ (by considering a limit ordinal $\lambda > \delta$ such that $a \in V_\lambda$ in the definition of
2.1. FROM REINHARDT CARDINALS UPWARD

$M$), and so there exists a $j \in \mathcal{E}(M)$ such that $\text{crit}(j) < \delta$; finally, since $a$ is definable in $M$ and $j^*M \subseteq M$, $j(a) = a$.

The following theorem provides the motivation for generalizing the notion of being a proto-Berkeley cardinal.

**Theorem 2.1.14.** Let $\delta_0$ be the least proto-Berkeley cardinal. Then the critical points of the witnessing embeddings are cofinal in $\delta_0$, i.e., for all transitive sets $M$ such that $\delta_0 \in M$ and for all $\eta < \delta_0$ there exists $j \in \mathcal{E}(M)$ with $\eta < \text{crit}(j) < \delta_0$.

Proof. For contradiction, suppose that $\eta_0 < \delta_0$ is the least ordinal for which the claim is false, i.e., there exists a transitive set $M_0$ such that $\delta_0 \in M_0$ and there does not exist a $j \in \mathcal{E}(M_0)$ with $\eta_0 < \text{crit}(j) < \delta_0$. Let $M$ be any transitive set such that $\eta_0 \in M$. By Lemma 2.1.12, there exists a transitive set $M'$ such that $\langle M_0, M, \eta_0 \rangle$ is definable in $M'$. Since $\delta_0 \in M'$, there exists $j' \in \mathcal{E}(M')$ with $\text{crit}(j') < \delta_0$. Since $j''M' \subseteq M'$, by definability we have that $j'((M_0, M, \eta_0)) = \langle M_0, M, \eta_0 \rangle$, and so, $j'$ fixes $M_0$, $M$ and $\eta_0$; therefore, $j' \upharpoonright M_0 \in \mathcal{E}(M_0)$ (because notice that $j''M_0 \subseteq j'(M_0) = M_0$) and, by the definition of $\eta_0$, $\text{crit}(j' \upharpoonright M_0) \leq \eta_0$. But $j'(\eta_0) = \eta_0$, hence $\text{crit}(j' \upharpoonright M_0) < \eta_0$. Similarly, $j' \upharpoonright M \in \mathcal{E}(M)$ and $\text{crit}(j' \upharpoonright M) < \eta_0$. It follows that $\eta_0$ is a proto-Berkeley cardinal, which is a contradiction.

**Definition 2.1.15.** Suppose $\alpha$ is an ordinal. An ordinal $\delta$ is an $\alpha$-proto-Berkeley cardinal if for all transitive sets $M$ such that $\delta \in M$ there exists $j \in \mathcal{E}(M)$ with $\alpha < \text{crit}(j) < \delta$.

The proof of Theorem 2.1.14 adapts to show the following more general result, motivating the definition of Berkeley cardinals:

**Theorem 2.1.16.** Suppose $\alpha$ is an ordinal. Let $\delta_\alpha$ be the least $\alpha$-proto-Berkeley cardinal. Then for all transitive sets $M$ such that $\delta_\alpha \in M$ and for all
2.1. FROM REINHARDT CARDINALS UPWARD

\( \eta < \delta \alpha \) there exists \( j \in \mathcal{E}(M) \) with \( \eta < \text{crit}(j) < \delta \).

**Definition 2.1.17.** A cardinal \( \delta \) is a **Berkeley cardinal** if for every transitive set \( M \) such that \( \delta \in M \) and for every ordinal \( \eta < \delta \) there exists \( j \in \mathcal{E}(M) \) with \( \eta < \text{crit}(j) < \delta \).

**Remark 2.1.18.** Notice that:

1. For each ordinal \( \alpha \), the least \( \alpha \)-proto-Berkeley cardinal is a Berkeley cardinal. So, the least Berkeley cardinal is also characterized as the least \( \alpha \)-proto-Berkeley cardinal, for every ordinal \( \alpha \).

2. If \( \delta \) is a limit of Berkeley cardinals then \( \delta \) is a Berkeley cardinal, i.e., the class of Berkeley cardinals is closed.

3. The property of being a Berkeley cardinal is a \( \Pi_2 \) property.

4. If \( \delta \) is a Berkeley cardinal then for all limit ordinals \( \lambda > \delta \), \( V_\lambda \) thinks that \( \delta \) is a Berkeley cardinal.

We focus on the least Berkeley cardinal, call it \( \delta_0 \). The next lemma will enable us to show some reflection phenomena occurring at \( \delta_0 \). Also, we prove that \( \delta_0 \) is not extendible.

**Lemma 2.1.19.** Let \( \delta_0 \) be the least Berkeley cardinal. Then for a tail of limit ordinals \( \beta \), if \( j \in \mathcal{E}(V_\beta) \) is such that \( \text{crit}(j) < \delta_0 \) then \( j(\delta_0) = \delta_0 \) and the set \( \{ \eta < \delta_0 : j(\eta) = \eta \} \) is cofinal in \( \delta_0 \) (i.e., \( \delta_0 \) is a limit of \( j \)-fixed points).

**Proof.** By assumption, every \( \delta < \delta_0 \) is not a proto-Berkeley cardinal, so there exists a transitive set \( M_\delta \) such that \( \delta \in M_\delta \) and there does not exist \( j \in \mathcal{E}(M_\delta) \) with \( \text{crit}(j) < \delta \); for each \( \delta < \delta_0 \), let \( \beta_\delta \) be least such that \( V_{\beta_\delta} \) contains such a witness \( M_\delta \). If \( \beta > \delta_0 \) is a limit ordinal such that \( \beta > \beta_\delta \) for all \( \delta < \delta_0 \), then \( V_\beta \) thinks that \( \delta_0 \) is a Berkeley cardinal and that any \( \delta < \delta_0 \) is not a proto-Berkeley cardinal (since \( V_\beta \) contains all of the witnesses), so \( V_\beta \) recognizes
that $\delta_0$ is the least proto-Berkeley cardinal; therefore, for any such $\beta$, $\delta_0$ is definable in $V_\beta$, and so, for any $j \in E(V_\beta)$, we have that $j(\delta_0) = \delta_0$. Let $\beta$ be in the above tail and suppose that $j \in E(V_\beta)$ is such that $\text{crit}(j) < \delta_0$. Assume, for contradiction, that the set $\{\eta < \delta_0 : j(\eta) = \eta\}$ is not cofinal in $\delta_0$; let $\eta_0 = \sup\{\eta < \delta_0 : j(\eta) = \eta\}$ and, for $i < \omega$, let $\eta_{i+1} = j(\eta_i)$. It follows that $\delta_0 = \sup\{\eta_i : i < \omega\}$, since the latter is a $j$-fixed point greater than $\eta_0$ and less than or equal to $\delta_0$ (as $\eta_i < \delta_0$ for all $i < \omega$). Let $M_0$ be a witness in $V_\beta$ to the fact that $\eta_0$ is not a proto-Berkeley cardinal, i.e., a transitive set containing $\eta_0$ such that there is no $j \in E(M_0)$ with $\text{crit}(j) < \eta_0$. For $i < \omega$, define $M_{i+1} = j(M_i)$; notice that $M_{i+1}$ turns to be a witness that $\eta_{i+1}$ is not a proto-Berkeley cardinal. For a tail of limit ordinals $\beta$, we have $j, M_0 \in V_\beta$, and since the sequence $\langle M_i : i < \omega \rangle$ is definable from these two elements, it is also $\langle M_i : i < \omega \rangle \in V_\beta$; moreover, by Lemma 2.1.12, there exists a transitive set $M$ such that $V_\beta$ and $\langle M_i : i < \omega \rangle$ are both definable in $M$, so that they are fixed by any $j \in E(M)$. Since $\delta_0 \in M$, we can let $j' \in E(M)$ be such that $\text{crit}(j') < \delta_0$. Then, we have that $j'' = j' | V_\beta \in E(V_\beta)$ is such that $j''(\langle M_i : i < \omega \rangle) = \langle M_i : i < \omega \rangle$ (as the sequence is definable in $M$ and is in the domain of $j''$) and $\text{crit}(j'') < \delta_0$; moreover, notice that $j''(\langle M_i : i < \omega \rangle) = \langle M_i : i < \omega \rangle$ implies $j''(M_i) = M_i$ for all $i < \omega$. Since $\delta_0 = \sup\{\eta_i : i < \omega\}$, $\text{crit}(j'') < \eta_i$ for some $i < \omega$; for such an $i$, $j''(M_i) = M_i$ and $j'' \upharpoonright M_i \in E(M_i)$ is such that $\text{crit}(j'' \upharpoonright M_i) < \eta_i$, contradicting that $M_i$ is a witness to the fact that $\eta_i$ is not a proto-Berkeley cardinal. \hfill \square

**Definition 2.1.20 (ZF).** A cardinal $\kappa$ is **extendible** if for all ordinals $\alpha$ there exist $\alpha'$ and an elementary embedding $j : V_{\kappa+\alpha} \to V_{j(\kappa)+\alpha'}$ such that $\text{crit}(j) = \kappa$ and $j(\kappa) > \alpha$.

**Theorem 2.1.21.** Suppose that $\delta_0$ is the least Berkeley cardinal. Then, $\delta_0$ is not extendible.
2.2. REFLECTION PHENOMENA

Proof. Let $\lambda > \delta_0$ be such that $V_\lambda \preceq_{\Sigma_2} V$. Since the property of being a Berkeley cardinal is a $\Pi_2$ property, $V_\lambda$ correctly recognizes Berkeley cardinals; in particular, $V_\lambda$ thinks that $\delta_0$ is a Berkeley cardinal. Suppose, for contradiction, that $\delta_0$ is extendible. Let $j : V_\lambda \rightarrow V_\lambda'$ be an elementary embedding such that $\text{crit}(j) = \delta_0$ and $j(\delta_0) > \lambda$. Since $V_\lambda'$ recognizes that $\delta_0$ is a Berkeley cardinal, $V_\lambda' \models \text{“There exists a Berkeley cardinal below } j(\delta_0)\text{”}$; it follows that $V_\lambda \models \text{“}\delta_0 \text{ is a limit of Berkeley cardinals”}$; in fact, for any fixed $\alpha < \delta_0$, since $V_\lambda' \models \text{“There exists a Berkeley cardinal between } j(\alpha) = \alpha \text{ and } j(\delta_0)\text{”}$, by elementarity we have that $V_\lambda \models \text{“There exists a Berkeley cardinal between } \alpha \text{ and } \delta_0\text{”}$. But $V_\lambda$ correctly recognizes Berkeley cardinals, and so, in $V$, $\delta_0$ is a limit of Berkeley cardinals, a contradiction. \qed

Although $\delta_0$ is not itself extendible, the hypothesis that there exists a Berkeley cardinal which is also super Reinhardt (and, therefore, extendible) turns to be consistent relative to a stronger version of a Berkeley cardinal, which will be called a limit club Berkeley cardinal; before introducing it, we have to define the notion of being a club Berkeley cardinal.

Definition 2.1.22. A cardinal $\delta$ is a club Berkeley cardinal if $\delta$ is regular and for all clubs $C \subseteq \delta$ and for all transitive sets $M$ such that $\delta \in M$, there exists $j \in \mathcal{E}(M)$ with $\text{crit}(j) \in C$.

Definition 2.1.23. A cardinal $\delta$ is a limit club Berkeley cardinal if $\delta$ is a club Berkeley cardinal which is a limit of Berkeley cardinals.

2.2 Reflection phenomena

We are now able to show the following relative consistency implications:

1. The least Berkeley cardinal rank-reflects an extendible cardinal and a Reinhardt cardinal.

3. A limit club Berkeley cardinal rank-reflects a Berkeley cardinal which is also super Reinhardt.

**Theorem 2.2.1.** Suppose that $\delta_0$ is the least Berkeley cardinal. Then there exists $\gamma < \delta_0$ such that $(V_\gamma, V_{\gamma+1}) \models \text{ZF}_2 + \text{"There exists an extendible cardinal and there exists a Reinhardt cardinal"}.$

**Proof.** By Lemma 2.1.19, for a tail of limit ordinals $\beta$, if $j \in \mathcal{E}(V_\beta)$ is such that $\text{crit}(j) < \delta_0$ then $j(\delta_0) = \delta_0$ and the set $\{ \eta < \delta_0 : j(\eta) = \eta \}$ is cofinal in $\delta_0$. Fix such a $\beta$ and $j \in \mathcal{E}(V_\beta)$. Let $\lambda = \sup \{ \kappa_i : i < \omega \}$, where $\kappa_0 = \text{crit}(j)$ and, for $i < \omega$, $\kappa_{i+1} = j(\kappa_i)$; we have that $j(\lambda) = \lambda$ and $\lambda < \delta_0$ (because $\lambda$ is the least $j$-fixed point greater than $\kappa_0$, while $\delta_0$ is a limit of $j$-fixed points). Since $\delta_0$ is a Berkeley cardinal, there exists $j' \in \mathcal{E}(V_{\delta_0+1})$ such that $\lambda < \text{crit}(j') < \delta_0$.

Let $\lambda' = \sup \{ \kappa'_i : i < \omega \}$, where $\kappa'_0 = \text{crit}(j')$ and, for $i < \omega$, $\kappa'_{i+1} = j'(\kappa'_i)$. The key point is that $V_{\lambda'} \models \text{ZF + "There exists an extendible cardinal"}$, and this is witnessed by $\kappa'_0$. In fact, suppose for contradiction that $V_{\lambda'} \models \text{"}\kappa'_0 \text{ is not extendible"}$, and let $\alpha < \lambda'$ be least such that in $V_{\lambda'}$ there do not exist $\alpha'$ and an elementary embedding $j : V_{\kappa_0'+\alpha} \to V_{j(\kappa'_0)+\alpha'}$ such that $\text{crit}(j) = \kappa'_0$ and $j(\kappa'_0) > \alpha$. Now, if we let $j_0 = j' \upharpoonright V_{\lambda'} \in \mathcal{E}(V_{\lambda'})$ and, for $i < \omega$, $j_{i+1} = j_0(j_i)$, we have that for some $i < \omega$, $j_i(\kappa'_0) > \alpha$; for such an $i$, the map $j_i \upharpoonright V_{\kappa_0'+\alpha} : V_{\kappa_0'+\alpha} \to V_{j_i(\kappa'_0)+\alpha(i)}$ is an elementary embedding such that $\text{crit}(j_i \upharpoonright V_{\kappa_0'+\alpha}) = \kappa'_0$ and $(j_i \upharpoonright V_{\kappa_0'+\alpha})(\kappa'_0) > \alpha$, contradicting the choice of $\alpha$. Thus, $\kappa'_0$ is indeed extendible in $V_{\lambda'}$. Since $V_{\kappa'_0} \prec V_{\lambda'}$ (as witnessed by $j'$) and $\kappa'_0 > \lambda$, it follows that $(V_{\kappa'_0}, V_{\kappa'_0+1}) \models \text{ZF}_2 + \text{"There exists an extendible cardinal greater than } \lambda \text{".}$ Let $\gamma \leq \kappa'_0$ be least such that $(V_\gamma, V_{\gamma+1}) \models \text{ZF}_2 + \text{"There exists an extendible cardinal greater than } \lambda \text{"}$, and let $\delta$ be the least extendible cardinal greater than $\lambda$ in $V_{\gamma+1}$; since $\gamma$ and $\delta$ are both definable from $\lambda$ and $j(\lambda) = \lambda$, $j$ fixes both $\gamma$ and $\delta$,
so \( j \restriction V_{\gamma+1} : V_{\gamma+1} \rightarrow V_{\gamma+1} \) is an elementary embedding with \( \text{crit}(j \restriction V_{\gamma+1}) = \text{crit}(j) = \kappa_0 \) (as \( \kappa_0 < \lambda < \delta \in V_{\gamma+1} \)), witnessing that \( \kappa_0 \) is a Reinhardt cardinal in \( V_{\gamma+1} \). In summary, we have shown that there exist \( \gamma < \delta_0 \) and \( \kappa_0 < \delta < \gamma \) such that \( (V_\gamma, V_{\gamma+1}) \models \text{ZF} + "\delta \text{ is extendible and } \kappa_0 \text{ is Reinhardt}" \), so, the proof is complete.

\[ \square \]

**Theorem 2.2.2.** Suppose that \( \delta \) is a club Berkeley cardinal. Then, \( (V_\delta, V_{\delta+1}) \models \text{ZF} + "\text{There exists a super Reinhardt cardinal}" \).

**Proof.** We begin by showing that for all transitive sets \( M \) such that \( V_{\delta+1} \in M \) there exists \( \kappa < \delta \) such that for all \( \alpha < \delta \) there exists \( j_\alpha \in \mathcal{E}(M) \) with \( \text{crit}(j_\alpha) = \kappa \) and \( j_\alpha(\kappa) > \alpha \). Suppose the claim fails and let \( M \) be a counterexample, i.e., a transitive set such that \( V_{\delta+1} \in M \) and for all \( \kappa < \delta \) there exists \( \alpha < \delta \) such that there does not exist \( j \in \mathcal{E}(M) \) with \( \text{crit}(j) = \kappa \) and \( j(\kappa) > \alpha \); for each \( \kappa < \delta \), let \( \alpha_\kappa \) be the least such \( \alpha \). Let \( C = \{ \gamma < \delta : \forall \kappa < \gamma \ (\alpha_\kappa < \gamma) \} \). Since \( \delta \) is regular, \( C \) is club in \( \delta \). Moreover, since \( C \subseteq \delta \in V_{\delta+1} \) and \( V_{\delta+1} \in M \), \( C \in M \).

Finally, since \( \delta \) is a club Berkeley cardinal and \( \delta \in M \), there exists \( j \in \mathcal{E}(M) \) such that \( \text{crit}(j) \in C \) and \( j(C) = C \): in fact, if we let \( M' \) be a transitive set such that both \( C \) and \( M \) are definable in \( M' \), then, since \( \delta \in M' \), we get that there exists \( j' \in \mathcal{E}(M') \) such that \( \text{crit}(j') \in C \), \( j'(C) = C \) and \( j'(M) = M \), and so \( j = j' \restriction M \in \mathcal{E}(M) \) is such that \( \text{crit}(j) = \text{crit}(j') \in C \) and \( j(C) = C \). Let \( \text{crit}(j) = \bar{\kappa} \). By elementarity, \( j(\bar{\kappa}) \in j(C) = C \); so, by the definition of \( C \), \( \bar{\kappa} < j(\bar{\kappa}) \) implies \( \alpha_{\bar{\kappa}} < j(\bar{\kappa}) \), contradicting the definition of \( \alpha_{\bar{\kappa}} \). Thus, we have shown that for all transitive sets \( M \) such that \( V_{\delta+1} \in M \) there exists \( \kappa < \delta \) such that for all \( \alpha < \delta \) there exists \( j_\alpha \in \mathcal{E}(M) \) with \( \text{crit}(j_\alpha) = \kappa \) and \( j_\alpha(\kappa) > \alpha \). Now, let \( M \) be any transitive set such that \( V_{\delta+1} \in M \), and let \( \kappa < \delta \) be as above; then, for each \( \alpha < \delta \), \( j_\alpha \restriction V_{\delta+1} \) is such that \( \text{crit}(j_\alpha \restriction V_{\delta+1}) = \kappa \) and \( (j_\alpha \restriction V_{\delta+1})(\kappa) > \alpha \), witnessing that \( (V_\delta, V_{\delta+1}) \models \text{ZF} + "\kappa \text{ is super Reinhardt}" \).
Theorem 2.2.3. Suppose that \( \delta \) is a limit club Berkeley cardinal. Then, 
\((V_\delta, V_{\delta+1}) \models ZF_2 + \text{"There exists a Berkeley cardinal that is super Reinhardt".}\)

Proof. The first claim we are going to prove is that for all transitive sets \( M \) such that \( V_{\delta+1} \in M \), and for all \( D \subseteq \delta \) which are club in \( \delta \), there exists \( \kappa \in D \) such that for all \( \alpha < \delta \) there exists \( j_\alpha \in E(M) \) such that \( \text{crit}(j_\alpha) = \kappa \) and \( j_\alpha(\kappa) > \alpha \). For contradiction, let \( (M, D) \) be a counterexample, i.e., let \( M \) be a transitive set such that \( V_{\delta+1} \in M \) and let \( D \subseteq \delta \) be a club in \( \delta \) such that for all \( \kappa \in D \) there exists \( \alpha < \delta \) such that there does not exist \( j \in E(M) \) with \( \text{crit}(j) = \kappa \) and \( j(\kappa) > \alpha \); for each \( \kappa \in D \), let \( \alpha_\kappa \) be the least such \( \alpha \). Let \( C = \{ \gamma < \delta : \forall \kappa \in D \cap \gamma \ (\alpha_\kappa < \gamma) \} \). Since \( \delta \) is regular, \( C \) is club in \( \delta \); thus, \( C \cap D \) is club in \( \delta \). Since \( \delta \) is a club Berkeley cardinal and \( \delta \in M \), there exists \( j \in E(M) \) such that \( \text{crit}(j) = \bar{\kappa} \in C \cap D, \ j(C) = C \) and \( j(D) = D \) (notice that \( C \) and \( D \) are both in \( M \)). By elementarity, \( j(\bar{\kappa}) \in j(C \cap D) = j(C) \cap j(D) = C \cap D \), and so, since \( \bar{\kappa} \in D \cap j(\bar{\kappa}) \), by the definition of \( C \) we have that \( \alpha_{\bar{\kappa}} < j(\bar{\kappa}) \), which contradicts the definition of \( \alpha_{\bar{\kappa}} \). Therefore, we have shown that for all transitive sets \( M \) such that \( V_{\delta+1} \in M \), and for all \( D \subseteq \delta \) which are club in \( \delta \), there exists \( \kappa \in D \) such that for all \( \alpha < \delta \) there exists \( j_\alpha \in E(M) \) such that \( \text{crit}(j_\alpha) = \kappa \) and \( j_\alpha(\kappa) > \alpha \). Now, let \( M \) be any transitive set such that \( V_{\delta+1} \in M \), let \( D \subseteq \delta \) be club in \( \delta \), and take \( \kappa \in D \) as above; again, for each \( \alpha < \delta \), \( j_\alpha \upharpoonright V_{\delta+1} \) is such that \( \text{crit}(j_\alpha \upharpoonright V_{\delta+1}) = \kappa \) and \( (j_\alpha \upharpoonright V_{\delta+1})(\kappa) > \alpha \), witnessing that \((V_\delta, V_{\delta+1}) \models ZF_2 + \text{"There exists a super Reinhardt cardinal } \kappa \in D \text{".}\) Since \( D \) was any club in \( \delta \), it follows that \((V_\delta, V_{\delta+1}) \models ZF_2 + \text{"There exist stationarily many super Reinhardt cardinals".}\). Since the class of Berkeley cardinals is closed and \( \delta \) is a limit of Berkeley cardinals, the Berkeley cardinals below \( \delta \) are club in \( \delta \), and so finally, \((V_\delta, V_{\delta+1}) \models ZF_2 + \text{"There exists a Berkeley cardinal that is super Reinhardt".}\) \( \square \)

2.3 The failure of Choice

The large cardinal axioms we are concerned with are in conflict with the Axiom of Choice: we are now going to illustrate the point at which the contradiction arises. We shall need a preliminary lemma.

**Definition 2.3.1.** Let $\delta_0$ be the least Berkeley cardinal. For any transitive set $M$ such that $\delta_0 \in M$, let $\kappa_M = \min\{\text{crit}(j) : j \in \mathcal{E}(M)\}$.

**Remark 2.3.2.** Notice that:

1. $\kappa_M$ is well-defined, since $\delta_0 \in M$ and so there exists $j \in \mathcal{E}(M)$.
2. $\kappa_M < \delta_0$.

**Lemma 2.3.3.** Let $\delta_0$ be the least Berkeley cardinal. Then for all $\eta < \delta_0$ there exists a transitive set $M_{\eta}$ such that $\delta_0 \in M_{\eta}$ and $\kappa_{M_{\eta}} > \eta$ (i.e., $\text{crit}(j) > \eta$ for all $j \in \mathcal{E}(M_{\eta})$).

**Proof.** For contradiction, let $\eta_0 < \delta_0$ be least such that for all transitive sets $M$ such that $\delta_0 \in M$, $\kappa_M \leq \eta_0$. Let $M$ be any transitive set such that $\eta_0 \in M$. Let $\tilde{M}$ be a transitive set such that $\delta_0 \in \tilde{M}$ and $M$ and $\eta_0$ are definable in $\tilde{M}$;...
let \( j \in \mathcal{E}(\hat{M}) \) be such that \( \text{crit}(j) = \kappa_{\hat{M}} \). By the definition of \( \eta_0 \), \( \text{crit}(j) = \kappa_{\hat{M}} \leq \eta_0 \); but \( j(\eta_0) = \eta_0 \), so \( \text{crit}(j) < \eta_0 \). Since \( j(M) = M \), \( j \restriction M \in \mathcal{E}(M) \); moreover, \( \text{crit}(j \restriction M) < \eta_0 \). Since \( M \) was an arbitrary set containing \( \eta_0 \), it follows that \( \eta_0 \) is a proto-Berkeley cardinal, which is a contradiction (recall that the least proto-Berkeley cardinal is \( \delta_0 \) itself).

**Definition 2.3.4.** For any cardinal \( \gamma \geq \omega \) and for any set \( X \neq \emptyset \), \( \gamma\text{-DC}(X) \) (\( \gamma \)-Dependent Choice on \( X \)) is the statement that for every function \( F : <\gamma \times X \to \mathcal{P}(X) \setminus \{\emptyset\} \) there exists a sequence \( f : \gamma \to X \) such that for all \( \alpha < \gamma \), \( f(\alpha) \in F(f \restriction \alpha) \). \( \gamma \text{-DC} \) (\( \gamma \)-Dependent Choice) is the statement that \( \gamma \text{-DC}(X) \) holds for all non-empty sets \( X \).

**Remark 2.3.5.** Recall that:

1. The Axiom of Choice (AC) is equivalent to the statement that \( \gamma \text{-DC} \) holds for all cardinals \( \gamma \geq \omega \).

2. \( \gamma \text{-DC} \) implies that every family \( \mathfrak{F} \) of non-empty sets such that \( |\mathfrak{F}| = \gamma \) has a choice function.

3. If \( \omega \leq \kappa < \gamma \), then \( \gamma \text{-DC} \) implies \( \kappa \text{-DC} \).

4. If \( \gamma \) is an infinite singular cardinal and \( \kappa \text{-DC} \) holds for all cardinals \( \kappa \) such that \( \omega \leq \kappa < \gamma \), then \( \gamma \text{-DC} \) holds.\(^4\)

**Theorem 2.3.6.** Suppose \( \delta_0 \) is the least Berkeley cardinal. Let \( \gamma = \text{cof}(\delta_0) \). Then, \( \gamma \text{-DC} \) fails.

**Proof.** Let \( \pi : \gamma \to \delta_0 \) be cofinal. For each \( \xi < \gamma \), let \( \beta_\xi \) be least such that \( V_{\beta_\xi} \) contains a transitive set \( M \) such that \( \delta_0 \in M \) and \( \kappa_M > \pi(\xi) \) (notice that, for every \( \xi < \gamma \), such an \( M \) does exist by Lemma 2.3.3). For each \( \xi < \gamma \), let \( \hat{M}_\xi = \{ M \in V_{\beta_\xi} : \text{“} M \text{ is transitive”} \land \delta_0 \in M \land \kappa_M > \pi(\xi) \} \); by the

\(^4\)See [2] ch. 8 for the proof.
2.3. THE FAILURE OF CHOICE

definition of $\beta_\xi$, we have that for every $\xi < \gamma$, $\tilde{M}_\xi \neq \emptyset$. For contradiction, assume that $\gamma$-DC holds. Then, there exists a sequence $\langle M_\xi : \xi < \gamma \rangle$ such that $M_\xi \in \tilde{M}_\xi$ for all $\xi < \gamma$; in fact: if $S = \bigcup_{\xi < \gamma} \tilde{M}_\xi$ and $F : \langle \gamma \rangle \rightarrow \mathcal{P}(S) \setminus \{\emptyset\}$ is such that $F(s) = \tilde{M}_\xi$ whenever $\xi < \gamma$ and $s$ is a $\xi$-sequence in $S$, then, by $\gamma$-DC, there exists a $\gamma$-sequence $f : \gamma \rightarrow S$ such that for all $\xi < \gamma$, $f(\xi) \in F(f \upharpoonright \xi) = \tilde{M}_\xi$. Let $M'$ be a transitive set such that the sequence $\langle M_\xi : \xi < \gamma \rangle$ is definable in $M'$. Let $j' \in \mathcal{E}(M')$ be such that $\text{crit}(j') < \delta_0$.

Since $j'(\langle M_\xi : \xi < \gamma \rangle) = \langle M_\xi : \xi < \gamma \rangle$, we have that $j'(\gamma) = \gamma$ and for all $\xi < \gamma$, if $j'(\xi) = \xi$ then $j'(M_\xi) = M_\xi$; so, for every such $\xi$, $j' \upharpoonright M_\xi \in \mathcal{E}(M_\xi)$, which implies $\kappa_{M'} \geq \kappa_{M_\xi} > \pi(\xi)$. Therefore, there cannot exist cofinally many $\xi < \gamma$ such that $j'(\xi) = \xi$ (otherwise, we would have $\kappa_{M'} \geq \delta_0 = \sup\{\pi(\xi) : \xi < \gamma\}$).

It follows that there exist $\eta_0 = \sup\{\xi < \gamma : j'(\xi) = \xi\} < \gamma$ and $\langle \eta_i : i < \omega \rangle$ such that $\eta_{i+1} = j'(\eta_i)$ and $\sup\{\eta_i : i < \omega\} = \gamma$. So, since $\delta_0 = \sup\{\pi(\xi) : \xi < \gamma\}$, we have that for every $\alpha < \delta_0$ there exists $i < \omega$ such that $\pi(\eta_i) \geq \alpha$, that is, $\delta_0 = \sup\{\pi(\eta_i) : i < \omega\}$. Now, let $M''$ be a transitive set such that the sequence $\langle M_{\eta_i} : i < \omega \rangle$ is definable in $M''$ and let $j'' \in \mathcal{E}(M'')$ be such that $\text{crit}(j'') < \delta_0$.

Then, $j''(\langle M_{\eta_i} : i < \omega \rangle) = \langle M_{\eta_i} : i < \omega \rangle$. But now $j''(M_{\eta_i}) = M_{\eta_i}$ for all $i < \omega$, hence $j'' \upharpoonright M_{\eta_i} \in \mathcal{E}(M_{\eta_i})$ for all $i < \omega$; it follows that $\kappa_{M''} \geq \kappa_{M_{\eta_i}} > \pi(\eta_i)$ for all $i < \omega$, and so, $\kappa_{M''} \geq \delta_0$, a contradiction.

At this point, the following key question arises:

**Key Question.** Which is the cofinality of the least Berkeley cardinal?
Chapter 3

Cofinality of the least Berkeley Cardinal

The aim of this chapter is to show that the fundamental question of the cofinality of the least Berkeley cardinal is undecidable. This leaves open a range of possibilities for the exact amount of choice that it makes sense to assume in the context of Berkeley cardinals in order to demand the consistency of the resulting theory. We briefly analyze these possibilities. In the end, we outline the motivation for our further investigation, developed in the next chapter: uncover the mathematical structure revealed by choiceless large cardinals. We assume the reader is familiar with the technique of forcing (a complete account of forcing can be found in [4]).

3.1 Forcing the cofinality to be countable

First, we prove that there exists a forcing extension in which the least Berkeley cardinal has countable cofinality. To begin, recall the following “lifting criterion” for elementary embeddings:

Lemma 3.1.1 (Lifting Criterion). Suppose $j : M \rightarrow N$ is an elementary
3.1. FORCING THE COFINALITY TO BE COUNTABLE

embedding of two transitive models of (a sufficiently large fragment of) ZF. Let \( P \in M \) and suppose \( G \subseteq P \) is \( M \)-generic and \( H \subseteq j(P) \) is \( N \)-generic. Then, \( j \) lifts to an elementary embedding \( j^* : M[G] \to N[H] \) (with \( j^*(G) = H \)) iff \( j^* G \subseteq H \).

**Theorem 3.1.2.** Assume ZF + BC.\(^1\) Then there exists a forcing extension \( V[G] \) of \( V \) such that \( V[G] \models ZF + BC + \text{“cof}(\delta_0) = \omega \) where \( \delta_0 \) is the least Berkeley cardinal (as computed in \( V[G] \)).

**Proof.** Let \( \gamma_0 = (\delta_0)^V \) denote the least Berkeley cardinal in \( V \). Suppose \( (\text{cof}(\gamma_0))^V > \omega \). Let \( (\mathbb{P}_{\gamma_0}, \leq_{\mathbb{P}_{\gamma_0}}) \) be the forcing whose conditions are of the form \( \langle \sigma, C \rangle \) where \( \sigma \in [S^\omega_{\gamma_0}]^\omega = \{ \sigma \subseteq S^\omega_{\gamma_0} : |\sigma| < \omega \} \) is a finite subset of \( S^\omega_{\gamma_0} = \{ \alpha < \gamma_0 : \text{cof}(\alpha) = \omega \} \) and \( C \) is an \( \omega \)-club in \( \gamma_0 \), i.e., \( C \) is an unbounded subset of \( \gamma_0 \) and \( C \) contains all its limit points less than \( \gamma_0 \) of cofinality \( \omega \). Let \( \leq_{\mathbb{P}_{\gamma_0}} = \leq \) be defined as follows: for all \( \langle \sigma_1, C_1 \rangle, \langle \sigma_2, C_2 \rangle \in \mathbb{P}_{\gamma_0}, \langle \sigma_2, C_2 \rangle \leq \langle \sigma_1, C_1 \rangle \) iff

1. \( C_2 \subseteq C_1 \),
2. \( \sigma_1 \subseteq \sigma_2 \),
3. \( \sigma_2 \cap \text{sup}(\sigma_1) = \sigma_1 \) (i.e., \( \sigma_2 \) end-extends \( \sigma_1 \)) and
4. \( \sigma_2 \setminus \sigma_1 \subseteq C_1 \).

Notice that \( \leq \) is transitive. Let \( G \subseteq \mathbb{P}_{\gamma_0} \) be \( V \)-generic, and let \( \sigma_G = \bigcup \{ \sigma : \exists C \ (\langle \sigma, C \rangle \in G) \} \). We claim that \( (\text{cof}(\gamma_0))^V[G] = \omega \). In fact, we have the following:

**Claim 1.** In \( V[G] \):

1. The order type of \( \sigma_G \) is \( \omega \).

\(^1\)We use BC as a shorthand for “There exists a Berkeley Cardinal”.
2. For all $C \in V$ such that $C$ is $\omega$-club in $\gamma_0$, $C \setminus \sigma_G$ is bounded.

1. Since each $\sigma$ is finite, it is clearly $\text{ot}(\sigma_G) \leq \omega$. But for all $n \in \omega$, there exists a condition $\langle \sigma, C \rangle \in G$ with $\text{ot}(\sigma) = n$: in fact, for $n \in \omega$, since any condition in $\mathbb{P}_{\gamma_0}$ can be extended to a condition $\langle \sigma, C \rangle$ such that $\text{ot}(\sigma) = n$, the set $\{\langle \sigma, C \rangle \in \mathbb{P}_{\gamma_0} : \text{ot}(\sigma) = n\}$ is dense, and so, it hits $G$. Therefore, $\text{ot}(\sigma_G) = \omega$.

2. First, notice that for all $C \in V$ such that $C$ is $\omega$-club in $\gamma_0$, there exists a condition $\langle \sigma, D \rangle \in G$ such that $D \subseteq C$: in fact, if $C \in V$ is an $\omega$-club in $\gamma_0$ and $\langle \sigma', C' \rangle \in \mathbb{P}_{\gamma_0}$, then $C \cap C'$ is an $\omega$-club in $\gamma_0$, and we have that $\langle \sigma', C \cap C' \rangle \leq \langle \sigma', C' \rangle$, so the set $D_C = \{\langle \sigma, D \rangle : D \subseteq C\}$ is dense in $\mathbb{P}_{\gamma_0}$, and, therefore, $G \cap D_C \neq \emptyset$. Now, let $C \in V$ be an $\omega$-club in $\gamma_0$. Then, there exists a condition $\langle \sigma, D \rangle \in G$ with $D \subseteq C$; it follows that $\langle \sigma, C \rangle \in G$ (as $\langle \sigma, D \rangle \leq \langle \sigma, C \rangle$), and for all further extensions $\langle \sigma'', C'' \rangle$, $\sigma'' \setminus \sigma \subseteq C$, hence $C \setminus \sigma_G$ is bounded.

It follows that in $V[G]$, $\sigma_G$ is a club in $\gamma_0$ of order type $\omega$. So, $(\text{cof}(\gamma_0))^{V[G]} = \omega$. It remains to prove that $V[G] \models \text{"\gamma_0 is a Berkeley cardinal"}$. We preliminarily show the following:

Claim 2. Either

1. $1_{\mathbb{P}_{\gamma_0}} \models_{\mathbb{P}_{\gamma_0}} \text{"\gamma_0 is a Berkeley cardinal"}$

or

2. $1_{\mathbb{P}_{\gamma_0}} \models_{\mathbb{P}_{\gamma_0}} \text{"\gamma_0 is not a Berkeley cardinal"}$. 

22
3.1. FORCING THE COFINALITY TO BE COUNTABLE

Proof. Either there exists a condition \( \langle \sigma_0, C_0 \rangle \) such that \( \langle \sigma_0, C_0 \rangle \Vdash_{\mathbb{P}_\gamma} \) “\( \gamma_0 \) is a Berkeley cardinal” or there exists a condition \( \langle \sigma_1, C_1 \rangle \) such that \( \langle \sigma_1, C_1 \rangle \Vdash_{\mathbb{P}_\gamma} \) “\( \gamma_0 \) is not a Berkeley cardinal”. Suppose \( \langle \sigma_0, C_0 \rangle \Vdash_{\mathbb{P}_\gamma} \) “\( \gamma_0 \) is a Berkeley cardinal”; then, \( \langle \emptyset, C_0 \rangle \Vdash_{\mathbb{P}_\gamma} \) “\( \gamma_0 \) is a Berkeley cardinal”: in fact, since \( \sigma_0 \) is in \( V \) (and hence in all generic extensions), for every \( G \subseteq \mathbb{P}_\gamma \) generic through \( \langle \sigma_0, C_0 \rangle \), \( G \setminus \sigma_0 \) is generic through \( \langle \emptyset, C_0 \rangle \) and \( V[G] = V[G \setminus \sigma_0] \), and, conversely, for every \( G \subseteq \mathbb{P}_\gamma \) generic through \( \langle \emptyset, C_0 \rangle \), \( G \cup \sigma_0 \) is generic through \( \langle \sigma_0, C_0 \rangle \) and \( V[G] = V[G \cup \sigma_0] \) (therefore, we actually have that \( \langle \sigma_0, C_0 \rangle \Vdash_{\mathbb{P}_\gamma} \) “\( \gamma_0 \) is a Berkeley cardinal” iff \( \langle \emptyset, C_0 \rangle \Vdash_{\mathbb{P}_\gamma} \) “\( \gamma_0 \) is a Berkeley cardinal”). Similarly, if \( \langle \sigma_1, C_1 \rangle \Vdash_{\mathbb{P}_\gamma} \) “\( \gamma_0 \) is not a Berkeley cardinal”, then \( \langle \emptyset, C_0 \rangle \Vdash_{\mathbb{P}_\gamma} \) “\( \gamma_0 \) is not a Berkeley cardinal”. Thus, there cannot exist \( \langle \sigma_0, C_0 \rangle \), \( \langle \sigma_1, C_1 \rangle \) \( \in \mathbb{P}_\gamma \) such that \( \langle \sigma_0, C_0 \rangle \Vdash_{\mathbb{P}_\gamma} \) “\( \gamma_0 \) is a Berkeley cardinal” and \( \langle \sigma_1, C_1 \rangle \Vdash_{\mathbb{P}_\gamma} \) “\( \gamma_0 \) is not a Berkeley cardinal”, otherwise we would have that \( \langle \emptyset, C_0 \rangle \Vdash_{\mathbb{P}_\gamma} \) “\( \gamma_0 \) is a Berkeley cardinal” and \( \langle \emptyset, C_1 \rangle \Vdash_{\mathbb{P}_\gamma} \) “\( \gamma_0 \) is not a Berkeley cardinal”, which is a contradiction because \( \langle \emptyset, C_0 \rangle \) and \( \langle \emptyset, C_1 \rangle \) are compatible conditions (in fact, \( \langle \emptyset, C_0 \cap C_1 \rangle \) extends both). So, the conditions in \( \mathbb{P}_\gamma \) that decide the statement \( \varphi_{\text{BC}} = \text{df} \) “\( \gamma_0 \) is a Berkeley cardinal” must decide it in the same way. Since for all formulas \( \varphi \) of the forcing language the set \( D_\varphi = \{ p \in \mathbb{P}_\gamma : p \Vdash_{\mathbb{P}_\gamma} \varphi \lor p \Vdash_{\mathbb{P}_\gamma} \neg \varphi \} \) is dense, we have that either \( D_{\varphi_{\text{BC}}}^+ = \{ p \in \mathbb{P}_\gamma : p \Vdash_{\mathbb{P}_\gamma} \varphi_{\text{BC}} \} \) is dense or \( D_{\varphi_{\text{BC}}}^- = \{ p \in \mathbb{P}_\gamma : p \Vdash_{\mathbb{P}_\gamma} \neg \varphi_{\text{BC}} \} \) is dense, and so, either \( 1_{\mathbb{P}_\gamma} \Vdash_{\mathbb{P}_\gamma} \varphi_{\text{BC}} \) or \( 1_{\mathbb{P}_\gamma} \Vdash_{\mathbb{P}_\gamma} \neg \varphi_{\text{BC}} \) (as for all formulas \( \varphi \), \( p \Vdash_{\mathbb{P}_\gamma} \varphi \) iff \( q \leq p : q \Vdash_{\mathbb{P}_\gamma} \varphi \) is dense). \( \square \)

Claim 3. \( 1_{\mathbb{P}_\gamma} \Vdash_{\mathbb{P}_\gamma} \varphi_{\text{BC}}. \)

Proof. For contradiction, assume not. Then, \( 1_{\mathbb{P}_\gamma} \Vdash_{\mathbb{P}_\gamma} \neg \varphi_{\text{BC}} \). So, let \( \langle \sigma_0, C_0 \rangle \in \mathbb{P}_\gamma \) and \( \tau \in \text{Name}_{\mathbb{P}_\gamma} \) be such that \( \langle \sigma_0, C_0 \rangle \Vdash_{\mathbb{P}_\gamma} \) “\( \tau \) is a transitive set such that \( \gamma_0 \in \tau \) and there exists \( \xi < \gamma_0 \) such that there does not exist a non-trivial elementary embedding \( j : \tau \to \tau \) with \( \xi < \text{crit}(j) < \gamma_0 \)”. Fix
3.1. FORCING THE COFINALITY TO BE COUNTABLE

such a $\xi$. Let $\eta >> \gamma_0$ be a limit ordinal such that $\tau \in V_\eta$ and $V_\eta \models ZF^*$, where $ZF^*$ indicates a big fragment of $ZF$ which suffices to implement the proof that $j$ lifts. Since $\gamma_0$ is a Berkeley cardinal in $V$, there exists an elementary embedding $j : V_\eta \rightarrow V_\eta$ such that $\xi < \text{crit}(j) < \gamma_0$, $j(\gamma_0) = \gamma_0$, $\hat{j}(\tau) = \tau$, $j([S^\omega_0]^{<\omega}) = [S^\omega_0]^{<\omega}$, $j(\mathbb{P}_{\gamma_0}) = \mathbb{P}_{\gamma_0}$, $j(\langle \sigma, C_0 \rangle) = \langle \sigma, C_0 \rangle$.

Let $C_j = \{ \alpha \in S^\omega_0 : j(\alpha) = \alpha \} = \{ \alpha < \gamma_0 : \text{cof}(\alpha) = \omega \text{ and } j(\alpha) = \alpha \}$.

By Lemma 2.1.19, $C_j$ is cofinal in $\gamma_0$; moreover, $C_j$ is $\omega$-club in $\gamma_0$ (in fact, if $\lambda < \gamma_0$ is a limit point of $C_j$ such that $\text{cof}(\lambda) = \omega$, then $j(\lambda) = \lambda \in C_j$), and we have that $\langle \sigma, C_0 \cap C_j \rangle \subseteq \langle \sigma, C_0 \rangle$. Now, let $G \subseteq \mathbb{P}_{\gamma_0}$ be a $V$-generic filter such that $\langle \sigma, C_0 \cap C_j \rangle \in G$. Then, $\langle \sigma, C_0 \rangle \in G$. Let $\sigma_G = \bigcup \{ \sigma : \exists C \ (\langle \sigma, C \rangle \in G) \}$.

Look at $j^{-1}G = \{ p \in \mathbb{P}_{\gamma_0} : j(p) \in G \}$. Let us show the following:

Subclaim. $G \subseteq j^{-1}G$.

Proof. First, notice that for all $\langle \sigma, C \rangle \in \mathbb{P}_{\gamma_0}$ such that $\langle \sigma, C \rangle \leq \langle \sigma, C_0 \cap C_j \rangle$, $j(\sigma) = \sigma$: in fact, $j(\sigma_0) = \sigma_0$ (as $j(\langle \sigma_0, C_0 \rangle) = \langle j(\sigma_0), j(C_0) \rangle = \langle \sigma_0, C_0 \rangle$) and $\sigma = \sigma_0^\check{\sigma}$, where $\sigma \setminus \sigma_0 = \check{\sigma} \subseteq C_0 \cap C_j \subseteq C_j$, but $j(\check{\sigma}) = \check{\sigma}$ (as $\check{\sigma} \in [C_j]^{<\omega}$ and $j$ is the identity on $[C_j]^{<\omega}$), so $j(\sigma) = j(\sigma_0^\check{\sigma}) = j(\sigma_0)^\check{j(\check{\sigma})} = \sigma_0^\check{j(\check{\sigma})} = \sigma$.

Moreover, for all $C \subseteq C_j$, $j^C \subseteq j(C)$. It follows that for all $\langle \sigma, C \rangle \in \mathbb{P}_{\gamma_0}$ such that $\langle \sigma, C \rangle \leq \langle \sigma, C_0 \cap C_j \rangle$, $\langle \sigma, C \rangle \leq j(\langle \sigma, C \rangle)$: in fact, if $\langle \sigma, C \rangle \leq \langle \sigma_0, C_0 \cap C_j \rangle$, then $C \subseteq C_0 \cap C_j \subseteq C_j$, and so $C \subseteq j(C)$, which implies $\langle \sigma, C \rangle \leq \langle \sigma, j(C) \rangle = \langle j(\sigma), j(C) \rangle = j(\langle \sigma, C \rangle)$. Now, take any $\langle \sigma, C \rangle \in G$. Then, there exists a condition $\langle \sigma', C' \rangle \in G$ which extends both $\langle \sigma, C \rangle$ and $\langle \sigma_0, C_0 \cap C_j \rangle$. Since $\langle \sigma', C' \rangle \leq \langle \sigma_0, C_0 \cap C_j \rangle$, we have that $\langle \sigma', C' \rangle \leq j(\langle \sigma', C' \rangle)$, hence $j(\langle \sigma', C' \rangle) \in G$; but by elementarity, $j(\langle \sigma', C' \rangle) \leq j(\langle \sigma, C \rangle)$, so $j(\langle \sigma, C \rangle) \in G$, which implies $\langle \sigma, C \rangle \in j^{-1}G$. Therefore, $G \subseteq j^{-1}G$. □

It follows that $j^G = \{ j(p) : p \in G \} \subseteq G$. So, by the “lifting criterion” we have that $j : V_\eta \rightarrow V_\eta$ lifts to an elementary embedding $j^* : V_\eta[G] \rightarrow V_\eta[G]$. Since $j^*(G) = G$ and $j^*(\tau) = j(\tau) = \tau$, we have that $j^*(\tau_G) = \tau_G$;
moreover, \( \xi < \text{crit}(j^*) = \text{crit}(j) < \gamma_0 \). Therefore, \( j^* \upharpoonright \tau_G : \tau_G \to \tau_G \) is an elementary embedding such that \( \xi < \text{crit}(j^* \upharpoonright \tau_G) < \gamma_0 \), contradicting the choice of \( \langle \sigma_0, C_0 \rangle \) and \( \tau \) as a counterexample to \( \gamma_0 \) being a Berkeley cardinal in \( V[G] \). This completes the proof that \( 1_{\mathbb{P}_{\gamma_0}} \models \varphi_{\text{BC}} \), i.e., for all \( V \)-generic \( G \subseteq \mathbb{P}_{\gamma_0} \), \( V[G] \models \text{“} \gamma_0 \text{ is a Berkeley cardinal”} \).

In summary, we have shown that if \( G \subseteq \mathbb{P}_{\gamma_0} \) is \( V \)-generic, then \( V[G] \models \text{“} \gamma_0 \text{ is a Berkeley cardinal”} + \text{“cof}(\gamma_0) = \omega \text{”} \). It remains to handle a final issue: although \( \gamma_0 \) is a Berkeley cardinal in \( V[G] \), it could be that \( \gamma_0 \) is not the least Berkeley cardinal in \( V[G] \). So, suppose \( \gamma_1 < \gamma_0 \) is the least Berkeley cardinal in \( V[G] \) and \( (\text{cof}(\gamma_1))^{V[G]} = \nu_1 > \omega \). Let \( p_0 \in G_0 = G \) be a condition that forces this, and consider the product forcing \( \mathbb{P}_{\gamma_0} \times \mathbb{P}_{\gamma_1} \); if \( G_0 \times G_1 \) is \( V \)-generic, then \( V[G_0 \times G_1] = V[G_0][G_1] \models \text{“} \gamma_1 \text{ is a Berkeley cardinal”} + \text{“cof}(\gamma_1) = \omega \text{”} \). However, again, it could be that \( \gamma_1 \) is not the least Berkeley cardinal in \( V[G_0][G_1] \), in which case, we continue. If the theorem continues to fail in the \( i^{th} \)-generic extension of \( V \), then we let \( p_i \in G_i, \gamma_i+1 \) and \( \nu_{i+1} \) be as above and we force with \( \mathbb{P}_{\gamma_0} \times \cdots \times \mathbb{P}_{\gamma_{i+1}} \); since \( \gamma_0, \ldots, \gamma_{i+1} \) are decreasing, this procedure must terminate at some finite stage \( i + 1 \), at which point \( V[G_0] \ldots [G_{i+1}] \) satisfies that the least Berkeley cardinal has countable cofinality.

\section{Independence from ZF}

The following theorem shows that it is consistent for the cofinality of the least Berkeley cardinal to be \( \omega_1 \), establishing the announced undecidability result.

\textbf{Theorem 3.2.1.} Assume \( \text{ZF} + \text{BC} + \text{DC} \).\footnote{\text{DC} is \( \omega \)-\text{DC}.} Then there exists a forcing extension \( V[G] \) of \( V \) such that \( V[G] \models \text{ZF} + \text{BC} + \text{DC} + \text{“cof}(\delta_0) = \omega_1 \), where \( \delta_0 \) is the least Berkeley cardinal (as computed in \( V[G] \)).
3.2. INDEPENDENCE FROM ZF

Proof. Let \( \gamma_0 = (\delta_0)^V \) denote the least Berkeley cardinal in \( V \). By Theorem 2.3.6, we have \( (\text{cof}(\gamma_0))^V \geq \omega_1 \). If \( (\text{cof}(\gamma_0))^V = \omega_1 \) then we are done. So, assume \( (\text{cof}(\gamma_0))^V > \omega_1 \). Let \( \langle \mathbb{P}_{\gamma_0}, \leq_{\mathbb{P}_{\gamma_0}} \rangle \) be the forcing whose conditions are of the form \( \langle \sigma, C \rangle \) where \( \sigma \in [S_{\omega_0}^\gamma]^\omega = \{ \sigma \subseteq S_{\omega_0}^\gamma : |\sigma| = \omega \} \) is a countable subset of \( S_{\omega_0}^\gamma = \{ \alpha < \gamma_0 : \text{cof}(\alpha) = \omega \} \) and \( C \) is an \( \omega \)-club in \( \gamma_0 \). Let \( \leq_{\mathbb{P}_{\gamma_0}} = \leq \) be defined by putting for all \( \langle \sigma_1, C_1 \rangle, \langle \sigma_2, C_2 \rangle \in \mathbb{P}_{\gamma_0}, \langle \sigma_2, C_2 \rangle \leq \langle \sigma_1, C_1 \rangle \) iff

1. \( C_2 \subseteq C_1 \),
2. \( \sigma_1 \subseteq \sigma_2 \),
3. \( \sigma_2 \cap \text{sup}(\sigma_1) = \sigma_1 \) (i.e., \( \sigma_2 \) end-extends \( \sigma_1 \)) and
4. \( \sigma_2 \setminus \sigma_1 \subseteq C_1 \).

It is immediate that \( \leq \) is transitive. Moreover, since we are assuming DC, we have the following:

Claim 1. \( \langle \mathbb{P}_{\gamma_0}, \leq_{\mathbb{P}_{\gamma_0}} \rangle \) is \( \omega \)-closed, i.e., for every decreasing \( \omega \)-sequence \( \langle p_n : n \in \omega \rangle \) of elements of \( \mathbb{P}_{\gamma_0} \) (i.e., such that \( m < n \rightarrow p_n \leq_{\mathbb{P}_{\gamma_0}} p_m \)) there exists \( q \in \mathbb{P}_{\gamma_0} \) such that \( q \leq_{\mathbb{P}_{\gamma_0}} p_n \) for all \( n \in \omega \).

Proof. Suppose \( \langle \langle \sigma_n, C_n \rangle : n \in \omega \rangle \) is a decreasing \( \omega \)-sequence in \( \mathbb{P}_{\gamma_0} \). Then, \( \langle \bigcup_{n \in \omega} \sigma_n, \bigcap_{n \in \omega} C_n \rangle \in \mathbb{P}_{\gamma_0} \): in fact, by DC, \( \bigcup_{n \in \omega} \sigma_n \in [S_{\omega}^\gamma]^\omega \) and \( \bigcap_{n \in \omega} C_n \) is an \( \omega \)-club in \( \gamma_0 \). Moreover, \( \langle \bigcup_{n \in \omega} \sigma_n, \bigcap_{n \in \omega} C_n \rangle \leq \langle \sigma_n, C_n \rangle \) for all \( n \in \omega \). □

Let \( G \subseteq \mathbb{P}_{\gamma_0} \) be \( V \)-generic, and let \( \sigma_G = \bigcup \{ \sigma : \exists C (\langle \sigma, C \rangle \in G) \} \). Since \( \mathbb{P}_{\gamma_0} \) is \( \omega \)-closed, we have that \( (\omega_1)^V[G] = (\omega_1)^V \). We show that \( (\text{cof}(\gamma_0))^V[G] \leq \omega_1 \).

In fact, the following holds:

Claim 2. In \( V[G] \):

1. The order type of \( \sigma_G \) is \( \omega_1 \).
2. For all \( C \in V \) such that \( C \) is \( \omega \)-club in \( \gamma_0 \), \( C \setminus \sigma_G \) is bounded.
3.2. INDEPENDENCE FROM ZF

1. Since each $\sigma$ is countable, it is clearly $\operatorname{ot}(\sigma_G) \leq \omega_1$. But for any $\alpha < \omega_1$, since every condition in $P_{\gamma_0}$ can be extended to a condition $\langle \sigma, C \rangle$ such that $\operatorname{ot}(\sigma) = \alpha$, the set $\{\langle \sigma, C \rangle \in P_{\gamma_0} : \operatorname{ot}(\sigma) = \alpha \}$ is dense, and so, there exists a condition $\langle \sigma, C \rangle \in G$ with $\operatorname{ot}(\sigma) = \alpha$. Therefore, $\operatorname{ot}(\sigma_G) = \omega_1$.

2. Let $C \in V$ be an $\omega$-club in $\gamma_0$. If $\langle \sigma', C' \rangle \in P_{\gamma_0}$, then $C \cap C'$ is an $\omega$-club in $\gamma_0$ and $\langle \sigma', C \cap C' \rangle \leq \langle \sigma', C' \rangle$; so, the set $\{\langle \sigma, D \rangle : D \subseteq C \}$ is dense in $P_{\gamma_0}$. Therefore, there exists a condition $\langle \sigma, D \rangle \in G$ such that $D \subseteq C$; it follows that $\langle \sigma, C \rangle \in G$, and for all further extensions $\langle \sigma'', C'' \rangle$, $\sigma'' \setminus \sigma \subseteq C$.

It follows that in $V[G]$, $\sigma_G$ is a club in $\gamma_0$ of order type $\omega_1$. So, $(\operatorname{cof}(\gamma_0))^{V[G]} \leq \omega_1$. In order to prove that $\gamma_0$ is still a Berkeley cardinal in $V[G]$, we preliminarily show the following:

Claim 3. Either

1. $1_{P_{\gamma_0}} \vDash_{P_{\gamma_0}} \text{"} \gamma_0 \text{ is a Berkeley cardinal\"}$

or

2. $1_{P_{\gamma_0}} \vDash_{P_{\gamma_0}} \text{"} \gamma_0 \text{ is not a Berkeley cardinal\"}$.

Proof. Either there exists a condition $\langle \sigma_0, C_0 \rangle$ such that $\langle \sigma_0, C_0 \rangle \vDash_{P_{\gamma_0}} \text{"} \gamma_0 \text{ is a Berkeley cardinal\"}$ or there exists a condition $\langle \sigma_1, C_1 \rangle$ such that $\langle \sigma_1, C_1 \rangle \vDash_{P_{\gamma_0}} \text{"} \gamma_0 \text{ is not a Berkeley cardinal\"}$. Notice that if $\langle \sigma_0, C_0 \rangle \vDash_{P_{\gamma_0}} \text{"} \gamma_0 \text{ is a Berkeley cardinal\"}$, then $\langle \emptyset, C_0 \rangle \vDash_{P_{\gamma_0}} \text{"} \gamma_0 \text{ is a Berkeley cardinal\"}$ (in fact, since $\sigma_0$ is in $V$, for every generic through $\langle \sigma_0, C_0 \rangle$ there is an equivalent generic through $\langle \emptyset, C_0 \rangle$, in the sense of yielding the same generic extension, and conversely). Likewise, if $\langle \sigma_1, C_1 \rangle \vDash_{P_{\gamma_0}} \text{"} \gamma_0 \text{ is not a Berkeley cardinal\"}$ then
3.2. INDEPENDENCE FROM ZF

\( \langle 0, C_1 \rangle \vDash_{P_{\gamma_0}} \text{“} \gamma_0 \text{ is not a Berkeley cardinal”} \). But \( \langle 0, C_0 \rangle \) and \( \langle 0, C_1 \rangle \) are compatible conditions, and so, every condition in \( P_{\gamma_0} \) that decides the statement \( \varphi_{BC} = \text{def} \ “\gamma_0 \text{ is a Berkeley cardinal”} \) must decide it in the same way. Since for all formulas \( \varphi \) of the forcing language the set \( D_\varphi = \{ p \in P_{\gamma_0} : p \vDash_{P_{\gamma_0}} \varphi \lor p \vDash_{P_{\gamma_0}} \neg \varphi \} \) is dense, we have that either \( D_{\varphi_{BC}}^+ = \{ p \in P_{\gamma_0} : p \vDash_{P_{\gamma_0}} \varphi_{BC} \} \) is dense or \( D_{\varphi_{BC}}^- = \{ p \in P_{\gamma_0} : p \vDash_{P_{\gamma_0}} \neg \varphi_{BC} \} \) is dense, namely, either \( 1_{P_{\gamma_0}} \vDash_{P_{\gamma_0}} \varphi_{BC} \) or \( 1_{P_{\gamma_0}} \vDash_{P_{\gamma_0}} \neg \varphi_{BC} \).

Claim 4. \( 1_{P_{\gamma_0}} \vDash_{P_{\gamma_0}} \varphi_{BC} \).

Proof. For contradiction, assume not. Then, \( 1_{P_{\gamma_0}} \vDash_{P_{\gamma_0}} \neg \varphi_{BC} \). So, let \( \langle \sigma_0, C_0 \rangle \in P_{\gamma_0} \) and \( \tau \in \text{Name}_{P_{\gamma_0}} \) be such that \( \langle \sigma_0, C_0 \rangle \vDash_{P_{\gamma_0}} \text{“} \tau \text{ is a transitive set such that } \gamma_0 \in \tau \text{ and there exists } \xi < \gamma_0 \text{ such that there does not exist a non-trivial elementary embedding } j : \tau \rightarrow \tau \text{ with } \xi < \text{crit}(j) < \gamma_0 \text{”} \). Fix such a \( \xi \). Let \( \eta >> \gamma_0 \) be a limit ordinal such that \( \tau \in V_\eta \) and \( V_\eta \vDash \text{ZF}^* \), where ZF* indicates a big fragment of ZF which suffices to implement the proof that \( j \) lifts. Since \( \gamma_0 \) is a Berkeley cardinal in \( V \), there exists an elementary embedding \( j : V_\eta \rightarrow V_\eta \) such that \( \xi < \text{crit}(j) < \gamma_0 \), \( j(\gamma_0) = \gamma_0 \), \( j(\tau) = \tau \), \( j([S_\omega^{\omega_0}]^\omega) = [S_\omega^{\omega_0}]^\omega \), \( j(P_{\gamma_0}) = P_{\gamma_0} \), \( j(\langle \sigma_0, C_0 \rangle) = \langle \sigma_0, C_0 \rangle \). Let \( C_j = \{ \alpha \in S_\omega^{\omega_0} : j(\alpha) = \alpha \} = \{ \alpha < \gamma_0 : \text{cof}(\alpha) = \omega \text{ and } j(\alpha) = \alpha \} \). By Lemma 2.1.19, \( C_j \) is cofinal in \( \gamma_0 \); moreover, \( C_j \) is \( \omega \)-club in \( \gamma_0 \), and we have that \( \langle \sigma_0, C_0 \cap C_j \rangle \leq \langle \sigma_0, C_0 \rangle \). Now, let \( G \subseteq P_{\gamma_0} \) be a \( V \)-generic filter such that \( \langle \sigma_0, C_0 \cap C_j \rangle \in G \), and let \( \sigma_G = \bigcup \{ \sigma : \exists C \ (\langle \sigma, C \rangle \in G) \} \). It follows that \( \langle \sigma_0, C_0 \rangle \in G \). Moreover:

Subclaim. \( G \subseteq j^{-1}“G” \).

Proof. First, notice that for all \( \langle \sigma, C \rangle \in P_{\gamma_0} \) such that \( \langle \sigma, C \rangle \leq \langle \sigma_0, C_0 \cap C_j \rangle \), \( j(\sigma) = \sigma \): in fact, \( j(\sigma_0) = \sigma_0 \) (as \( j(\langle \sigma_0, C_0 \rangle) = \langle j(\sigma_0), j(C_0) \rangle = \langle \sigma_0, C_0 \rangle \)) and \( \sigma = \sigma_0 \circ \sigma \), where \( \sigma \setminus \sigma_0 = \sigma \subseteq C_0 \cap C_j \subseteq C_j \), but \( j(\sigma) = \sigma \) (as \( \sigma \in [C_j]^\omega \) and \( j \) is the identity on \( [C_j]^\omega \)), so \( j(\sigma) = j(\sigma_0 \circ \sigma) = j(\sigma_0) \circ j(\sigma) = \).
\[ \sigma \cdot \bar{\sigma} = \sigma. \] Moreover, for all \( C \subseteq C_j, C = j^*C \subseteq j(C). \) It follows that for all \( \langle \sigma, C \rangle \in \mathbb{P}_{\gamma_0} \) such that \( \langle \sigma, C \rangle \leq \langle \sigma_0, C_0 \cap C_j \rangle, \) \( \langle \sigma, C \rangle \leq j(\langle \sigma, C \rangle) \): in fact, if \( \langle \sigma, C \rangle \leq \langle \sigma_0, C_0 \cap C_j \rangle, \) then \( C \subseteq C_0 \cap C_j \subseteq C_j, \) so \( C \subseteq j(C), \) which implies \( \langle \sigma, C \rangle \leq \langle \sigma, j(C) \rangle = \langle j(\sigma), j(C) \rangle = j(\langle \sigma, C \rangle). \) Now, take any \( \langle \sigma, C \rangle \in G. \) Then, there exists a condition \( \langle \sigma', C'' \rangle \in G \) which extends both \( \langle \sigma, C \rangle \) and \( \langle \sigma_0, C_0 \cap C_j \rangle. \) Since \( \langle \sigma', C'' \rangle \leq \langle \sigma_0, C_0 \cap C_j \rangle, \) we have that \( \langle \sigma', C'' \rangle \leq j(\langle \sigma', C'' \rangle), \) hence \( j(\langle \sigma', C'' \rangle) \in G; \) but by elementarity, \( j(\langle \sigma', C'' \rangle) \leq j(\langle \sigma, C \rangle), \) so \( j(\langle \sigma, C \rangle) \in G, \) which implies \( \langle \sigma, C \rangle \in j^{-1} G. \) Therefore, \( G \subseteq j^{-1} G. \) \( \square \)

It follows that \( j^* G \subseteq G. \) So, by the “lifting criterion” we have that \( j : V_\eta \rightarrow V_\eta \) lifts to an elementary embedding \( j^* : V_\eta[G] \rightarrow V_\eta[G]. \) Since \( j^*(G) = G \) and \( j^*(\tau) = j(\tau) = \tau, \) we have that \( j^*(\tau_0) = \tau_G; \) moreover, \( \xi < \text{crit}(j^*) = \text{crit}(j) < \gamma_0. \) Therefore, \( j^* : \tau_G \rightarrow \tau_G \) is an elementary embedding such that \( \xi < \text{crit}(j^* \upharpoonright \tau_G) < \gamma_0, \) contradicting the choice of \( \langle \sigma_0, C_0 \rangle \) and \( \tau \) as a counterexample to \( \gamma_0 \) being a Berkeley cardinal in \( V[G]. \) This completes the proof that \( 1_{\mathbb{P}_{\gamma_0}} \models \varphi_{BC}, \) i.e., for all \( V \)-generic \( G \subseteq \mathbb{P}_{\gamma_0}, V[G] \models \text{“} \gamma_0 \text{ is a Berkeley cardinal”}. \) \( \square \)

To summarize, we have shown that if \( G \subseteq \mathbb{P}_{\gamma_0} \) is \( V \)-generic, then \( V[G] \models \text{“} \gamma_0 \text{ is a Berkeley cardinal”} + \text{“} \cof(\gamma_0) \leq \omega_1. \) Notice that, since DC is preserved, if \( \gamma_0 \) is still the least Berkeley cardinal in \( V[G], \) then it is also \( \cof(\gamma_0)^{V[G]} \geq \omega_1, \) and so, we are done. Therefore, it remains to handle the case that \( (\delta_0)^{V[G]} < \gamma_0. \) So, suppose \( \gamma_1 < \gamma_0 \) is the least Berkeley cardinal in \( V[G]. \) Since \( V[G] \models \text{DC}, \) \( (\cof(\gamma_1))^{V[G]} = \nu_1 \geq \omega_1. \) If \( \nu_1 = \omega_1 \) then we are done. So, assume \( \nu_1 > \omega_1. \) Let \( p_0 \in G_0 = G \) be a condition that forces this, and consider the product forcing \( \mathbb{P}_{\gamma_0} \times \mathbb{P}_{\gamma_1}; \) if \( G_0 \times G_1 \) is \( V \)-generic, then \( V[G_0 \times G_1] = V[G_0]|G_1] \models \text{“} \gamma_1 \text{ is a Berkeley cardinal”} + \text{“} \cof(\gamma_1) \leq \omega_1. \) However, again, it could be that \( \gamma_1 \) is not the least Berkeley cardinal in \( V[G_0]|G_1], \) and in which case, we continue. If the theorem continues to fail in the \( i^{th} \text{-} \)generic extension of \( V, \)
then we let \( p_i \in G_i \), \( \gamma_{i+1} \) and \( \nu_{i+1} \) be as above and we force with \( P_{\gamma_0} \times \cdots \times P_{\gamma_{i+1}} \); since \( \gamma_0, \ldots, \gamma_{i+1} \) are decreasing, this procedure must terminate at some finite stage \( i + 1 \), at which point \( V[G_0] \ldots [G_{i+1}] \) satisfies that the least Berkeley cardinal has cofinality less than or equal to \( \omega_1 \), which implies, by DC, that the cofinality is equal to \( \omega_1 \).

\[ \square \]

3.3 Toward a very deep Inconsistency

From the results achieved so far, we know that:

1. the cofinality of the least Berkeley cardinal is connected with the failure of AC (the lower the cofinality, the greater the failure) and

2. the cofinality of the least Berkeley cardinal is independent of ZF.

The natural question arises as to whether the statement “cof(\( \delta_0 \)) = \( \omega \)” is weaker in consistency strength than the statement “cof(\( \delta_0 \)) = \( \omega_1 \)” (where \( \delta_0 \) is the least Berkeley cardinal), and so on. If so, then we would have a hierarchy of increasingly strong hypotheses, enclosing increasingly big fragments of AC:

- \( \text{ZF + BC + “cof}(\delta_0) = \omega” \)
- \( \text{ZF + BC + DC + “cof}(\delta_0) = \omega_1” \)
- \( \text{ZF + BC + \( \omega_1 \)-DC + “cof}(\delta_0) = \omega_2” \)

\[ \cdots \]

- \( \text{ZF + BC + <}(\delta_0)-\text{DC + “cof}(\delta_0) = \delta_0”^3 \)

\(^3<\delta_0\)-DC is \( \gamma\)-DC for all \( \gamma < \delta_0 \).
Notice that if \( ZF + BC + "\text{cof}(\delta_0) > \omega" \) proves that there exists \( \gamma < \delta_0 \) such that \( V_\gamma \models ZF + BC + "\text{cof}(\delta_0) = \omega" \), then it would follow that \( ZF + BC + DC \) is inconsistent.

The more appealing motivation to investigate choiceless large cardinals is indeed that of finding an even deeper inconsistency result. This search for “deep inconsistency” points toward a new proof of inconsistency of a large cardinal axiom in just \( ZF \) (after Kunen’s proof that Reinhardt cardinals are inconsistent with \( AC \)). And in fact, it follows from results of Woodin in [6] that

**If the HOD Conjecture holds then there are no Berkeley cardinals.**

Recall that the HOD Conjecture is the following statement:

**HOD Conjecture.** There exists a proper class of uncountable regular cardinals \( \kappa \) such that for all \( \gamma < \kappa \), if \( \gamma \) is an infinite cardinal in HOD and \( (2^{\gamma})^{\text{HOD}} < \kappa \) then there exists a partition \( \langle S_\alpha : \alpha < \gamma \rangle \) of \( \{ \xi < \kappa : \text{cof}(\xi) = \omega \} \) into stationary sets such that \( \langle S_\alpha : \alpha < \gamma \rangle \in \text{HOD} \).

In particular, a consequence of the assumption that the HOD Conjecture is provable contradicts Theorem 2.2.1. Therefore, a proof of the HOD Conjecture would actually lead to a new very deep inconsistency result.

But what if choiceless large cardinals enable us to developing a remarkable mathematical theory?

The rest of this dissertation is aimed to show that this could indeed be the case. In fact, we will be concerned with the structural properties of \( L(V_{\delta+1}) \) under the assumption that \( \delta \) is a singular limit of Berkeley cardinals which are limit of extendibles. Of course, it could be that this pattern leads to inconsistency (and anyhow, this would be very interesting, in the spirit traced above); on the other side, it could also be that this investigation provides us with motivations
for arguing in favour of the consistency (with ZF) of choiceless large cardinal axioms (which would be really interesting as well) . . .
Chapter 4

Berkeley Cardinals and the
structure of $L(V_{\delta+1})$

In the present chapter we look at the structure theory of $L(V_{\delta+1})$ when $\delta$ satisfies a certain large cardinal property which is proved to be consistent by a limit club Berkeley cardinal: it turns out that, in the resulting framework, we are able to get several remarkable $I_0$-like results. First, we provide a proof of the Coding Lemma, and the subsequent “strong-limitness” of $\Theta$. We are then interested in showing the regularity of $\delta^+$. Finally, we are concerned with the existence of measurable cardinals in $L(V_{\delta+1})$ (recall that $I_0$ is the statement that there exists an elementary embedding $j : L(V_{\lambda+1}) \rightarrow L(V_{\lambda+1})$ with critical point below $\lambda$; for a sample of the $I_0$ case see [7]).

4.1 The framework provided by a limit club Berkeley

Before starting our analysis of $L(V_{\delta+1})$, we preliminarily need to justify the large cardinal axiom we will require to hold at $\delta$. Precisely, we will assume that
δ is a singular limit of Berkeley cardinals each of which is a limit of extendibles. And our first task is to show that this hypothesis is in fact consistent by a limit club Berkeley cardinal.

Remark 4.1.1. Notice that if δ∗ is a limit club Berkeley cardinal then 
\((V_{δ^*}, V_{δ^*+1}) \models ZF_2 + \text{"There exists a proper class of Berkeley cardinals" + "There exists a proper class of extendible cardinals".}\)

The next lemma is just a consequence of the fact that extendible cardinals are Σ₃ reflecting.

Lemma 4.1.2. Suppose κ is extendible, and there exists a Berkeley cardinal above κ. Then, κ is a limit of Berkeley cardinals.

Corollary 4.1.3. Suppose κ is extendible, and there exists a Berkeley cardinal above κ. Then, κ is a Berkeley cardinal.

Proof. Immediate, since the class of Berkeley cardinals is closed.

Corollary 4.1.4. Suppose κ is a limit of extendibles. Then, κ is a Berkeley cardinal iff κ is a limit of Berkeley cardinals.

Corollary 4.1.5. Suppose κ is a limit of extendibles, and there exists a Berkeley cardinal above κ. Then, κ is a Berkeley cardinal (in fact, κ is a limit of Berkeley cardinals).

By Remark 4.1.1 and Corollary 4.1.5, we immediately have the following:

Corollary 4.1.6. Suppose that δ∗ is a limit club Berkeley cardinal. Then, 
\((V_{δ^*}, V_{δ^*+1}) \models ZF_2 + \text{"There exists δ such that δ is a limit of Berkeley cardinals which are limit of extendibles".}\)

There is an important feature of extendible cardinals we have to point out here: as showed by Woodin in [6], extendibles enable to force choice. Moreover, the forcing in question preserves extendibles and Berkeley cardinals. In particular,
4.1. THE FRAMEWORK PROVIDED BY A LIMIT CLUB BERKELEY

in our case, assuming \( \delta \) is a limit of Berkeley cardinals each of which is a limit of extendible cardinals and \( \text{cof}(\delta) < \delta \), we can force DC past the cofinality of \( \delta \) and preserve that \( \delta \) is a limit of Berkeley cardinals which are limit of extendibles. And in fact, in carrying out the study of \( L(V_{\delta+1}) \) we will assume \( (\text{cof}(\delta))^{+}\)-DC.

The following theorem synthesizes the results we will establish in the rest of the chapter. We first recall the definition of \( \Theta \).

**Definition 4.1.7.** \( \Theta = \Theta^{L(V_{\delta+1})} = \sup\{ \alpha : \exists \pi : V_{\delta+1} \xrightarrow{onto} \alpha (\pi \in L(V_{\delta+1})) \} \).

**Theorem 4.1.8.** Suppose \( \delta \) is a limit of Berkeley cardinals which are limit of extendibles. Suppose \( \text{cof}(\delta) < \delta \). Assume \( (\text{cof}(\delta))^{+}\)-DC.\(^1\) Then:

1. \( L(V_{\delta+1}) \models \text{"The Coding Lemma"}. \)
2. \( L(V_{\delta+1}) \models \text{"For all } \alpha < \Theta \text{ there exists a surjection } \rho : V_{\delta+1} \xrightarrow{onto} \mathcal{P}(\alpha)\"}. \)
3. \( L(V_{\delta+1}) \models \text{"}\delta^+ \text{ is regular}". \)
4. \( L(V_{\delta+1}) \models \text{"}\delta^+ \text{ is measurable"}. \)
5. \( L(V_{\delta+1}) \models \text{"}\Theta \text{ is limit of measurable cardinals"}. \)

Throughout this chapter we will refer to the assumption of Theorem 4.1.8 as the theory \( T^* \):

**Definition 4.1.9.** \( T^* = \text{df "} \delta \text{ is a limit of Berkeley cardinals which are limit of extendibles" + \text{"cof}(\delta) < } \delta \text{" + } (\text{cof}(\delta))^{+}\)-DC. \)

\(^1\)Notice that the assumption of \( (\text{cof}(\delta))^{+}\)-DC implies \( L(V_{\delta+1}) \models (\text{cof}(\delta))^{+}\)-DC.
4.2 The Coding Lemma and the size of $\Theta$

As observed after introducing the Berkeley hierarchy, the distinctive feature of the work environment provided by Berkeley cardinals lies in the fact that we can arrange elementary embeddings fixing any given set. This will also be used in showing that the weaker version of the Coding Lemma holds in $L(V_{\delta+1})$; the Coding Lemma will follow (notice that in the $I_0$ case the proof of the Coding Lemma employs $\lambda$-DC, while we don’t have $\delta$-DC here).

**Lemma 4.2.1 (Weak Coding Lemma).** Assume $T^*$. Suppose $\alpha < \Theta$. Then there exists $\Gamma \subseteq P(V_{\delta+1} \times V_{\delta+1})$ such that:

1. “$\Gamma$ is small”, i.e., there exists $\pi : V_{\delta+1} \xrightarrow{onto} \Gamma$;
2. if $Z \subseteq V_{\delta+1}$, $\leq$ is a pre-well-ordering of $Z$ of length $\alpha$, and $W \subseteq Z \times V_{\delta+1}$, then there exists $W^* \subseteq W$ such that:

   (a) $W^* \in \Gamma$;

   (b) for cofinally many $\eta < \alpha$, if $Z_\eta$ is the $\eta$-component and $W \cap Z_\eta \times V_{\delta+1} \neq \emptyset$, then $W^* \cap Z_\eta \times V_{\delta+1} \neq \emptyset$.

**Proof.** Fix $\alpha < \Theta$. Let $\beta_0 < \Theta$. Start with $\Gamma = L_{\beta_0}(V_{\delta+1})$. If $L_{\beta_0}(V_{\delta+1})$ doesn’t witness the Weak Coding Lemma at $\alpha$, then there exists a counterexample $\langle Z, \rho, W \rangle$ with $Z \subseteq V_{\delta+1}$, $\rho : Z \xrightarrow{onto} \alpha$ (the norm associated to the pre-well-ordering serving as a counterexample) and $W \subseteq Z \times V_{\delta+1}$, and we try $L_{\beta_1}(V_{\delta+1})$; if $L_{\beta_1}(V_{\delta+1})$ doesn’t witness the Weak Coding Lemma at $\alpha$, then we try $L_{\beta_2}(V_{\delta+1})$, and so forth (notice that, although we cannot choose at any step a counterexample, we can certainly choose successively ordinals $\beta_i < \Theta$ for which $L_{\beta_i}(V_{\delta+1})$ doesn’t witness the Weak Coding Lemma at $\alpha$). For $i$ limit, we let $\beta_i = \text{af} \sup \{ \beta_j : j < i \}$. We claim that the sequence $\langle \beta_i : i < \delta \rangle$ is not defined, i.e., there exists $i < \delta$ such that $L_{\beta_i}(V_{\delta+1})$ witnesses
4.2. THE CODING LEMMA AND THE SIZE OF \( \Theta \)

the Weak Coding Lemma at \( \alpha \). For contradiction, suppose \( \langle \beta_i : i < \delta \rangle \) is defined. Since \( \delta \) is a Berkeley cardinal, there exists a non-trivial elementary embedding \( j : L(V_{\delta+1}) \to L(V_{\delta+1}) \) such that \( \text{cof}(\delta) < \text{crit}(j) < \delta, j(\delta) = \delta, j(\alpha) = \alpha \) and \( j(\langle \beta_i : i < \delta \rangle) = \langle \beta_i : i < \delta \rangle \). Let \( \text{crit}(j) = \kappa; \) we have that \( j(\beta_\kappa) = \beta_{j(\kappa)} \). Since \( L_{\beta_\kappa}(V_{\delta+1}) \) doesn’t witness the Weak Coding Lemma at \( \alpha \), there exists a counterexample \( \langle Z, \rho, W \rangle; \) by elementarity, \( \langle j(Z), j(\rho), j(W) \rangle \) is a counterexample for \( L_{\beta_{j(\kappa)}}(V_{\delta+1}) \) to be witness of the Weak Coding Lemma at \( j(\alpha) = \alpha \). Now, notice that \( W \in L_{\beta_{\kappa+1}}(V_{\delta+1}) \) and \( \beta_{\kappa+1} \ll j(\kappa) \). Look at \( j^\ast W \).

To compute \( j^\ast W \), we only need \( j \restriction V_\delta \) (as \( W \subseteq Z \times V_{\delta+1} \subseteq V_{\delta+1} \times V_{\delta+1} \) and \( j \restriction V_{\delta+1} \) is defined by \( j \restriction V_\delta \); but \( j \restriction V_\delta \in V_{\delta+1} \), so \( j^\ast W \in L_{\beta_{\kappa+1}}(V_{\delta+1}) \subseteq L_{\beta_{j(\kappa)}}(V_{\delta+1}) \) (in fact, \( j^\ast W \) is definable from the parameters \( j \restriction V_\delta \in V_{\delta+1} \) and \( W \in L_{\beta_{\kappa+1}}(V_{\delta+1}) \)). Moreover, \( j^\ast W \subseteq j(W) \) and \( j^\ast \alpha \) is cofinal in \( j(\alpha) \) (as \( j(\alpha) = \alpha \)). It follows that for cofinally many \( \eta < j(\alpha) = \alpha \), if there exists \( \langle a, b \rangle \in j(W) \) such that \( j(\rho)(a) = \eta \) then there exists \( \langle a, b \rangle \in j^\ast W \) such that \( j(\rho)(a) = \eta \). Therefore, \( j^\ast W \) satisfies the Weak Coding Lemma at \( \alpha \), contradicting the fact that \( \langle j(Z), j(\rho), j(W) \rangle \) was a counterexample for \( L_{\beta_{j(\kappa)}}(V_{\delta+1}) \) to be witness of the Weak Coding Lemma at \( \alpha \).

Theorem 4.2.2 (Coding Lemma). Assume \( T^* \). Suppose \( \alpha < \Theta \). Then there exists \( \Gamma \subseteq \mathcal{P}(V_{\delta+1} \times V_{\delta+1}) \) such that:

1. “\( \Gamma \) is small”, i.e., there exists \( \pi : V_{\delta+1} \xrightarrow{\text{onto}} \Gamma \);

2. if \( Z \subseteq V_{\delta+1}, \leq \) is a pre-well-ordering of \( Z \) of length \( \alpha \) and \( W \subseteq Z \times V_{\delta+1} \), then there exists \( W^* \subseteq W \) such that:

   a) \( W^* \in \Gamma \);

   b) for all \( \eta < \alpha \), if \( Z_\eta \) is the \( \eta \)-component and \( W \cap Z_\eta \times V_{\delta+1} \neq \emptyset \), then \( W^* \cap Z_\eta \times V_{\delta+1} \neq \emptyset \).
4.2. THE CODING LEMMA AND THE SIZE OF $\Theta$

Proof. For contradiction, assume that the Coding Lemma is false. Let $\alpha_0$ be
the least such that the Coding Lemma fails in $L(V_{\delta+1})$. Notice that if the
Coding Lemma holds for $\alpha$, then the Coding Lemma holds for $\alpha + 1$ (in fact,
if $W \cap Z_{\alpha} \times V_{\delta+1} \neq \emptyset$, then we just choose an element in this set and add it to
the set $W^*$ which satisfies the Coding Lemma at $\alpha$). So, $\alpha_0$ must be limit. For
every $\alpha < \alpha_0$, let $\beta_{\alpha} < \Theta$ be such that $L_{\beta_{\alpha}}(V_{\delta+1})$ witnesses the Coding Lemma
at $\alpha$. Then, choose $\beta < \Theta$ large enough so that $\Gamma = L_{\beta}(V_{\delta+1})$ witnesses the
Coding Lemma for all $\alpha < \alpha_0$ and the Weak Coding Lemma at $\alpha_0$. Now, let
$\beta_0 > \beta$ be such that in $L_{\beta_0}(V_{\delta+1})$ there exists a map $\pi_0 : V_{\delta+1} \overset{onto}{\longrightarrow} L_{\beta}(V_{\delta+1})$.
We claim that $L_{\beta_0}(V_{\delta+1})$ witnesses the Coding Lemma at $\alpha_0$. Let $Z \subseteq V_{\delta+1}$,
$\rho : Z \overset{onto}{\longrightarrow} \alpha_0$ and $W \subseteq Z \times V_{\delta+1}$; for all $\alpha < \alpha_0$, let $W_{\alpha} = W \cap Z_{\alpha} \times V_{\delta+1}$.
Let $Z^* = \{ x \in V_{\delta+1} : \pi_0(x) \subseteq W \}$, and define $\rho^* : Z^* \rightarrow \alpha_0$ such that
$\rho^*(x)$ is the least $\alpha < \alpha_0$ such that $\pi_0(x)$ is not good at $\alpha$, i.e., $W_{\alpha} \neq \emptyset$ but
$\pi_0(x) \cap Z_{\alpha} \times V_{\delta+1} = \emptyset$. First, notice that $\rho^*$ is well-defined: in fact, for every
$x \in Z^*$, either $\pi_0(x)$ satisfies the Coding Lemma at $\alpha_0$ (in which case, we are
done) or there exists $\alpha < \alpha_0$ such that $\pi_0(x)$ is not good at $\alpha$. Moreover, $\rho^*$ is
onto: in fact, for any $\alpha < \alpha_0$, since $L_{\beta}(V_{\delta+1})$ witnesses the Coding Lemma at
$\alpha$, there exists $W^* \in L_{\beta}(V_{\delta+1})$ as in the statement of the Coding Lemma, but
$\pi_0$ is onto, so $W^* = \pi_0(x)$ for some $x \in V_{\delta+1}$, and since $W^* \subseteq W$, we actually
have that $W^* = \pi_0(x)$ for some $x \in Z^*$ and $\pi_0(x)$ is good at $\eta$ for all $\eta < \alpha$.
Now, let $W^* = Z^* \times V_{\delta+1}$. By the Weak Coding Lemma, there exists $Y^* \subseteq Z^*$
such that $Y^* \in L_{\beta}(V_{\delta+1})$ and $\rho^*``Y^* \subseteq Z^* = \alpha_0$. Finally, let
$Y = \bigcup_{x \in Y^*} \pi_0(x)$. Then, $Y \subseteq W$ and $Y \in L_{\beta_0+1}(V_{\delta+1})$. Moreover, let us show
that if $W_{\alpha} \neq \emptyset$, it is also $Y \cap Z_{\alpha} \times V_{\delta+1} \neq \emptyset$. The point is that for all $\alpha < \alpha_0$
there exists $x \in Y^*$ such that $\pi_0(x)$ is good at $\alpha$: in fact, for every $\alpha < \alpha_0$
there exists $x \in Y^*$ such that $\rho^*(x) > \alpha$, and since $\rho^*(x)$ is the least such
that $\pi_0(x)$ is not good, $\pi_0(x)$ is good at $\alpha$. It follows that $Y = \bigcup_{x \in Y^*} \pi_0(x)$
is good at $\alpha$ for all $\alpha < \alpha_0$. Therefore, $Y$ satisfies the Coding Lemma at
4.3. REGULARITY OF $\delta^+$

$\alpha_0$, and so, $L_{\beta_0+1}(V_{\delta+1})$ witnesses the Coding Lemma at $\alpha_0$, contradicting our assumption.

A remarkable consequence of the Coding Lemma is the following result concerning the size of $\Theta$.

**Corollary 4.2.3.** Assume $T^*$. Then in $L(V_{\delta+1})$, for all $\alpha < \Theta$ there exists $\rho : V_{\delta+1} \overset{onto}{\rightarrow} P(\alpha)$.

**Proof.** Let $\alpha < \Theta$ and $\pi : V_{\delta+1} \overset{onto}{\rightarrow} \alpha$. Let $\beta < \Theta$ be the least such that $\pi \in L_\beta(V_{\delta+1})$. Let $L_{\beta^*}(V_{\delta+1})$ witness the Coding Lemma at $\alpha$, and let $\gamma = \max\{\beta, \beta^*\}$. For every $X \subseteq \alpha$, let $X^* = \{\langle a, \emptyset \rangle \in V_{\delta+1} \times V_{\delta+1} : \pi(a) \in X\}$. Then, by the Coding Lemma, there exists $W^* \subseteq X^*$ such that $W^* \in L_\gamma(V_{\delta+1})$ and for all $\eta < \alpha$, if there exists $\langle a, b \rangle \in X^*$ such that $\pi(a) = \eta$ then there exists $\langle a, b \rangle \in W^*$ such that $\pi(a) = \eta$. Since $\pi$ is a surjection, for every $\eta \in X$ there exists $\langle a, b \rangle \in X^*$ such that $\pi(a) = \eta$; so, we have that $\{\pi(a) : \exists b (\langle a, b \rangle \in W^*)\} = X$. It follows that $X \in L_{\gamma+1}(V_{\delta+1})$. But $X$ was an arbitrary subset of $\alpha$, hence $P(\alpha) \subseteq L_{\gamma+1}(V_{\delta+1})$, and since there exists $\rho : V_{\delta+1} \overset{onto}{\rightarrow} L_{\gamma+1}(V_{\delta+1})$, the proof is complete. \qed

### 4.3 Regularity of $\delta^+$

We are now going to show that $\delta^+$ is a regular cardinal in $L(V_{\delta+1})$. It will follow that $V_\delta$ cannot be mapped cofinally into $\delta^+$. In fact, by the following lemma the existence of such a cofinal map would imply that $\delta$ can be mapped cofinally into $\delta^+$.

**Lemma 4.3.1.** Assume $T^*$. Suppose $\delta < \kappa < \Theta$ and there exists $\pi : V_\delta \rightarrow \kappa$ cofinal. Then there exists $\pi^* : \delta \rightarrow \kappa$ cofinal.

**Proof.** By assumption, $\sup \pi^* V_\delta = \kappa$. Since $\sup \pi^* V_\delta = \sup_{\alpha < \delta} \{\sup \pi^* V_\alpha\}$, we can reduce to the case that there exists $\pi : V_\alpha \rightarrow \kappa$ cofinal with $\alpha < \delta$. Look
4.3. REGULARITY OF $\delta^+$

at $\text{HOD}^{L(V_{\delta+1})}_{\{\pi,V_\alpha\}}$, containing all the sets which are hereditarily ordinal definable with parameters $\pi$ and $V_\alpha$ in $L(V_{\delta+1})$. Notice that $\text{HOD}^{L(V_{\delta+1})}_{\{\pi,V_\alpha\}} \models \text{ZFC}$. Let $G \subseteq \text{Coll}((\text{cof}(\delta))^+, V_\alpha)$ be $V$-generic. Then, $\text{HOD}^{L(V_{\delta+1})[G]}_{\{\pi,V_\alpha\}} \models \text{ZFC}$. Since the forcing $\text{Coll}((\text{cof}(\delta))^+, V_\alpha)$ is homogeneous, we have that $\text{HOD}^{L(V_{\delta+1})[G]}_{\{\pi,V_\alpha\}} = \text{HOD}^{L(V_{\delta+1})}_{\{\pi,V_\alpha\}}$ (in fact, each of the two models can be defined into the other).

Let $\mathbb{B} = \mathcal{P}(\mathcal{P}(\alpha)) \cap OD^{L(V_{\delta+1})[G]}_{\{\pi,V_\alpha\}} = \{ A \subseteq \mathcal{P}(\alpha) : A \in OD^{L(V_{\delta+1})[G]}_{\{\pi,V_\alpha\}} \}$. Then, $\mathbb{B}$ is ordinal definable from $\pi$ and $V_\alpha$, and there exist $\mathbb{B}^* \in \text{HOD}^{L(V_{\delta+1})[G]}_{\{\pi,V_\alpha\}}$ and an isomorphism $\rho : \mathbb{B}^* \cong \mathbb{B}$ such that $\rho$ is ordinal definable from $\pi$ and $V_\alpha$. For every $X \subseteq \alpha$, let $G_X = \{ A \in \mathbb{B} : X \in A \}$ and $G^*_X = \rho^{-1}G_X = \{ B \in \mathbb{B}^* : \rho(B) \in G_X \}$. By Vopěnka’s basic argument, $G^*_X$ is $\text{HOD}^{L(V_{\delta+1})[G]}_{\{\pi,V_\alpha\}}$-generic for $\mathbb{B}^*$ and $\text{HOD}^{L(V_{\delta+1})[G]}_{\{\pi,V_\alpha\}}[G^*_X] = \text{HOD}^{L(V_{\delta+1})[G]}_{\{\pi,V_\alpha,X\}}$. Let us show the following:

**Claim.** There exists $\pi^* : \mathbb{B}^* \rightarrow \kappa$ cofinal such that $\pi^* \in OD^{L(V_{\delta+1})}_{\{\pi,V_\alpha\}}$.

**Proof.** First, notice that in $\text{HOD}^{L(V_{\delta+1})[G]}_{\{\pi,V_\alpha\}}$, every $a \in V_\alpha$ is coded by some $X \subseteq \alpha$. For every $\xi \in \pi^*V_\alpha$, let $A_\xi = \{ X \subseteq \alpha : \text{"X codes some } a \in V_\alpha \text{"} \} \in \mathcal{P}(\mathcal{P}(\alpha))$; then, for every $\xi \in \pi^*V_\alpha$, $A_\xi$ is ordinal definable with parameters $\pi$ and $V_\alpha$, i.e., $A_\xi \in OD^{L(V_{\delta+1})[G]}_{\{\pi,V_\alpha\}}$, and so, $A_\xi \in \mathbb{B}$. Therefore, there exists $e : \mathbb{B} \xrightarrow{onto} \pi^*V_\alpha$ such that $e \in OD^{L(V_{\delta+1})[G]}_{\{\pi,V_\alpha\}}$. It follows that $e \circ \rho : \mathbb{B}^* \xrightarrow{onto} \pi^*V_\alpha$ and $e \circ \rho \in OD^{L(V_{\delta+1})[G]}_{\{\pi,V_\alpha\}}$, which implies $e \circ \rho \in \text{HOD}^{L(V_{\delta+1})[G]}_{\{\pi,V_\alpha\}} = \text{HOD}^{L(V_{\delta+1})}_{\{\pi,V_\alpha\}}$. Thus, there exists $\pi^* : \mathbb{B}^* \rightarrow \kappa$ cofinal such that $\pi^* \in OD^{L(V_{\delta+1})}_{\{\pi,V_\alpha\}}$.

Since $|\mathbb{B}^*| < \delta$, we are done.  

**Lemma 4.3.2.** Assume $T^*$. Then, $\text{cof}(\delta^+) > \delta$, i.e., $\delta^+$ is regular (in $V$, and so, in $L(V_{\delta+1})$).

**Proof.** For contradiction, suppose $\text{cof}(\delta^+) < \delta$. Then, there exist $\kappa < \delta$ and $\pi : \kappa \rightarrow \delta^+$ cofinal. Since $\delta$ is limit of extendibles, we can choose an extendible $\gamma$ such that $\kappa < \gamma < \delta$. Now, pick $\eta >> \delta$ such that $V_\eta \prec_{\text{suff}} V$ (sufficiently
4.4. MEASURABILITY OF $\delta^+$

In showing that $\delta^+$ is measurable (i.e., there exists a $\delta^+$-complete ultrafilter on $\delta^+$), we will repeatedly employ the following result from [6]:

**AC-Lemma.** Suppose $\gamma$ is an extendible cardinal. Then for all $\alpha < \gamma$, there exists a partial order $\mathbb{P} \in V_\gamma$ such that $\mathbb{P}$ is cof($\delta$)-closed and there exists a strongly inaccessible cardinal $\epsilon$ such that $\alpha < \epsilon < \gamma$ and $V^\mathbb{P} \models \epsilon$-DC + “$\epsilon$ is strongly inaccessible”.

**Theorem 4.4.1.** Assume $T^*$. Then:

1. $V \models "\delta^+ \text{ is measurable}"$.

2. $L(V_{\delta+1}) \models "\delta^+ \text{ is measurable}"$.
Proof. Fix \( \delta_0 < \delta \) such that \( \delta_0 > \text{cof}(\delta) \) is a Berkeley cardinal and a limit of extendibles. Let \( \lambda < \delta^+ \) be an infinite regular cardinal such that \( \lambda \) is regular in \( L(V_{\delta + 1}) \). Let \( S^\delta_\lambda = S = \{ \alpha < \delta^+ : (\text{cof}(\alpha))^{L(V_{\delta + 1})} = \lambda \} \). Let \( \mathcal{E} = \{ j : V_\delta \to V_\delta : \text{cof}(\delta) < \text{crit}(j) < \delta_0 \wedge j(\delta_0) = \delta_0 \wedge j(\lambda) = \lambda \land "j extends canonically to } \hat{j} : V_{\delta + 1} \to V_{\delta + 1}" \}. Notice that, for all \( j \in \mathcal{E} \), the canonical extension \( \hat{j} \) is unique, as \( \hat{j}(A) = \bigcup_{\alpha < \delta} j(A \cap V_\alpha) \) for all \( A \subseteq V_\delta \).

Let \( S = \{ \alpha < \delta + \lambda : \text{cof}(\alpha) = \lambda \} \). Let \( E = \{ j : V_\delta \to V_\delta : \text{cof}(\delta) < \text{crit}(j) < \delta_0 \wedge j(\delta_0) = \delta_0 \wedge j(\lambda) = \lambda \land \forall \alpha \in \mathcal{E} \} \). Notice that, for all \( j \in E \), the canonical extension \( \hat{j} \) is uniquely determined, as \( \hat{j}(A) = \bigcup_{\alpha < \delta} j(A \cap V_\alpha) \) for all \( A \subseteq V_\delta \).

For any \( X \subseteq \mathcal{E} \) such that there exists \( \pi : V_\delta \xrightarrow{onto} \mathcal{X} \) (i.e., such that \( \mathcal{X} \) is small), let \( I_X = \{ \alpha < \delta^+ : \text{cof}(\alpha)^{L(V_{\delta + 1})} = \lambda \land (j(\alpha) = \alpha \forall j \in X) \} \). Now, let \( \mathcal{F}_\mathcal{E} \) be the filter generated by \( \{ I_X : X \subseteq \mathcal{E} \land \exists \pi : V_\delta \xrightarrow{onto} \mathcal{X} \} \), that is, let \( \mathcal{F}_\mathcal{E} = \{ X \subseteq \delta^+ : \exists \mathcal{X} \subseteq \mathcal{E} \land I_X \subseteq X \} \). Notice that \( S \in \mathcal{F}_\mathcal{E} \) and \( \mathcal{F}_\mathcal{E} \upharpoonright S \) is a filter on \( S \); moreover, \( \mathcal{F}_\mathcal{E} \) is correctly computed by \( L(V_{\delta + 1}) \), i.e., \( (\mathcal{F}_\mathcal{E})^V \cap L(V_{\delta + 1}) = (\mathcal{F}_\mathcal{E})^{L(V_{\delta + 1})} \) (in fact, \( L(V_{\delta + 1}) \) has all the embeddings \( j : V_\delta \to V_\delta \) and \( \mathcal{F}_\mathcal{E} \) is generated by sets which are in \( L(V_{\delta + 1}) \)). Let us show that the filter \( \mathcal{F}_\mathcal{E} \) is \( V_\delta \)-complete (in fact, \( V_{\delta^+} \)-complete) and there exists a partition of \( S \) into \( <\delta_0 \)-many \( \mathcal{F}_\mathcal{E} \)-positive sets on each of which the filter \( \mathcal{F}_\mathcal{E} \) is an ultrafilter.

Claim 1. In \( V \):

1. \( \mathcal{F}_\mathcal{E} \) is \( V_\delta \)-complete, i.e., for all \( \alpha < \delta \), for all \( \rho : V_\alpha \to \mathcal{F}_\mathcal{E} \), \( \bigcap \rho \upharpoonright V_\alpha \in \mathcal{F}_\mathcal{E} \).

2. \( \mathcal{F}_\mathcal{E} \) is \( V_{\delta^+} \)-complete.

Proof. Work in \( V \).

1. Fix \( \alpha < \delta \) and choose an extendible \( \gamma \) such that \( \alpha < \gamma < \delta \). By the AC-Lemma, there exists a pair \( (\mathbb{P}, \epsilon) \in V_\gamma \) such that \( \mathbb{P} \) is \( \text{cof}(\delta) \)-closed, \( \alpha < \epsilon < \gamma, \epsilon \) is strongly inaccessible and \( V^\mathbb{P} \models \epsilon \text{-DC} + \text{"} \epsilon \text{ is strongly inaccessible"} \). Fix \( \rho : V_\alpha \to \mathcal{F}_\mathcal{E} \), and let \( G \subseteq \mathbb{P} \) be \( V \)-generic. Then, in \( V[G] \), there exists a function \( F : V_\alpha \to V \) such that for all \( a \in V_\alpha, F(a) = (\mathcal{X}_a, \pi_a) \in V \) where \( \mathcal{X}_a \subseteq \mathcal{E} \), \( \pi_a : V_\delta \xrightarrow{onto} \mathcal{X}_a \) and \( I_{\mathcal{X}_a} \subseteq \rho(a) \)
4.4. MEASURABILITY OF $\delta^+$

(by $\epsilon$-DC). So, let $\tau \in V$ be a term for $F$ and choose $p \in G$ such
that $p \Vdash \tau$ is a function, $\text{dom}(\tau) = V_\alpha$ and for all $a \in V_\alpha$, $\tau(a) = \langle \mathcal{X}_a, \pi_a \rangle \in V$, $\mathcal{X}_a \subseteq \mathcal{E}$, $\pi_a : V_\delta \overset{onto}{\rightarrow} \mathcal{X}_a$ and $I_{\mathcal{X}_a} \subseteq \rho(a)$”. Now, let
$\mathcal{Y} = \bigcup\{\mathcal{X} \subseteq \mathcal{E} : \exists q < p \exists a \in V_\alpha \exists \pi \in V (q \Vdash \tau(a) = \langle \mathcal{X}, \pi \rangle)\}$. Define a
map $e : \mathbb{P} \times V_\alpha \times V_\delta \rightarrow \mathcal{Y}$ such that $e((q, a, b)) = j$ iff $q \Vdash \tau(a) = \langle \mathcal{X}, \pi \rangle$ and $\pi(b) = j$. Since $e$ is a surjection and since we can map $V_\delta$ onto its
domain, we get that there exists a surjection from $V_\delta$ onto $\mathcal{Y}$; it follows
that $I_\mathcal{Y} \in \mathcal{F}_\mathcal{E}$, but $I_\mathcal{Y} = \{\alpha < \delta^+ : (\text{cof}(\alpha))^{L(V_{\delta+1})} = \lambda \wedge (j(\alpha) = \alpha \forall j \in \mathcal{Y})\} = \bigcap\{I_\mathcal{X} : \mathcal{X} \subseteq \mathcal{E} \land \exists q < p \exists a \in V_\alpha \exists \pi \in V (q \Vdash \tau(a) = \langle \mathcal{X}, \pi \rangle)\} \subseteq \bigcap \rho^a V_\alpha$, hence $\bigcap \rho^a V_\alpha \in \mathcal{F}_\mathcal{E}$. Therefore, $\mathcal{F}_\mathcal{E}$ is $V_\delta^+$-complete.

2. In order to show that $\mathcal{F}_\mathcal{E}$ is $V_\delta^+$-complete, let $\pi : V_\delta \rightarrow \mathcal{F}_\mathcal{E}$. We have that
for all $\alpha < \delta$, $\bigcap \pi^a V_\alpha \in \mathcal{F}_\mathcal{E}$; we need to prove that $\bigcap \pi^a V_\delta \in \mathcal{F}_\mathcal{E}$. Let $e : \text{cof}(\delta) \rightarrow \delta$ be cofinal. Since $\bigcap \pi^a V_{e(\alpha)} \in \mathcal{F}_\mathcal{E}$ for all $\alpha < \text{cof}(\delta)$, $\text{cof}(\delta) < \delta$ and $\mathcal{F}_\mathcal{E}$ is $V_\delta$-complete, we have that $\bigcap_{\alpha < \text{cof}(\delta)}(\bigcap \pi^a V_{e(\alpha)}) \in \mathcal{F}_\mathcal{E}$; but
$\bigcap \pi^a V_\delta = \bigcap_{\alpha < \text{cof}(\delta)}(\bigcap \pi^a V_{e(\alpha)})$ (in fact, by $V_\delta = \bigcup_{\alpha < \text{cof}(\delta)} V_{e(\alpha)}$, $\bigcap \pi^a V_\delta = \bigcap \pi^a (\bigcup_{\alpha < \text{cof}(\delta)} V_{e(\alpha)}) = \bigcap (\bigcup_{\alpha < \text{cof}(\delta)} \pi^a V_{e(\alpha)}) = \bigcap (\bigcup_{\alpha < \text{cof}(\delta)} \pi^a V_{e(\alpha)})$, and so, we are done.

\[ \square \]

**Claim 2.** There exists a partition of $S$, $\langle T_\alpha : \alpha < \Omega \rangle$, into $\mathcal{F}_\mathcal{E}$-positive sets
such that $\Omega < \delta_0$ and $\mathcal{F}_\mathcal{E} \upharpoonright T_\alpha$ is an ultrafilter for all $\alpha < \Omega$.

**Proof.** Pick $\eta > \delta$ such that $V_\eta \prec_{\text{suff.}} V$. Let $\gamma$ be an extendible cardinal such
that $\delta_0 < \gamma < \delta$. Then, there exists $\pi : V_{\eta+1} \rightarrow V_{\pi(\eta)+1}$ such that $\text{crit}(\pi) = \gamma$
and $\pi(\gamma) > \eta$. Since $\mathcal{F}_\mathcal{E}$ is $V_\gamma$-complete and $S \in \mathcal{F}_\mathcal{E}$, by elementarity, it follows
that $\pi(\mathcal{F}_\mathcal{E}) = \pi(V_\delta) = V_{\pi(\delta)}$-complete and $\pi(S) \in \pi(\mathcal{F}_\mathcal{E})$; so, since $\mathcal{F}_\mathcal{E} \in V_\eta$ and
$\pi(\delta) > \pi(\gamma) > \eta$, we have that $\bigcap \pi^a \mathcal{F}_\mathcal{E} \in \pi(\mathcal{F}_\mathcal{E})$. Therefore, $\bigcap \pi^a \mathcal{F}_\mathcal{E} \cap \pi(S) \neq \emptyset$. For each $\alpha \in \bigcap \pi^a \mathcal{F}_\mathcal{E} \cap \pi(S)$, let $U_\alpha = \{X \subseteq \delta^+ : \alpha \in \pi(X)\}$. It follows

\[ \text{Recall that a set } T \subseteq \delta^+ \text{ is } \mathcal{F}_\mathcal{E}\text{-positive iff the complement of } T \text{ is not in } \mathcal{F}_\mathcal{E}. \]
that for each $\alpha \in \bigcap \pi^+ F \cap \pi(S)$, $U_\alpha$ is an ultrafilter on $\delta^+$ extending $F_\mathcal{E}$; in fact:

1. Since $\alpha \in \bigcap \pi^+ F \cap \pi(S) \subseteq \pi(\delta^+)$, $\delta^+ \in U_\alpha$.

2. Since $\alpha \notin \pi(\emptyset) = \emptyset$, $\emptyset \notin U_\alpha$.

3. If $X_1, X_2 \in U_\alpha$, then $\alpha \in \pi(X_1) \cap \pi(X_2) = \pi(X_1 \cap X_2)$, so $X_1 \cap X_2 \in U_\alpha$.

4. If $X_1 \in U_\alpha$ and $X_2 \subseteq \delta^+$ is such that $X_1 \subseteq X_2$, then $\alpha \in \pi(X_1) \subseteq \pi(X_2)$, so $X_2 \in U_\alpha$.

5. For any $X \subseteq \delta^+$ such that $\alpha \notin \pi(X)$, $\alpha \in \pi(\delta^+) \setminus \pi(X) = \pi(\delta^+ \setminus X)$, so $\delta^+ \setminus X \in U_\alpha$.

6. Since $\alpha \in \pi(X)$ for all $X \in F_\mathcal{E}$, $U_\alpha \supset F_\mathcal{E}$.

Moreover, each $U_\alpha$ is $V_\gamma$-complete, i.e., for all $\beta < \gamma$ and $\rho : V_\beta \to U_\alpha$, $\bigcap \rho^+ V_\beta \in U_\alpha$; in fact: if $\beta < \gamma$ and $\rho : V_\beta \to U_\alpha$, then $\pi(\rho) : V_{\pi(\beta)} = V_\beta \to \pi(U_\alpha)$ is such that for all $x \in V_\beta$, $\pi(\rho)(x) = \pi(\rho(\pi(x))) = \pi(\rho(x))$; but for all $x \in V_\beta$, $\rho(x) \in U_\alpha$, so for all $x \in V_\beta$, $\alpha \in \pi(\rho(x)) = \pi(\rho(x))$, which means that $\alpha \in \bigcap \pi(\rho)^+ V_\beta = \pi(\bigcap \rho^+ V_\beta)$, hence $\bigcap \rho^+ V_\beta \in U_\alpha$. Furthermore, if $U \supset F_\mathcal{E}$ is a $V_\gamma$-complete ultrafilter on $\delta^+$, then $\pi(U) \supset \pi(F_\mathcal{E})$ is $V_{\pi(\gamma)}$-complete, so $\bigcap \pi^+ U \in \pi(U)$, and if $\alpha \in \bigcap \pi^+ U \neq \emptyset$, then we have that $U \subseteq U_\alpha$, which implies $U = U_\alpha$; in other words, $W = \{ U_\alpha : \alpha \in \bigcap \pi^+ F \cap \pi(S) \}$ contains all the $V_\gamma$-complete ultrafilters on $\delta^+$ extending $F_\mathcal{E}$. In order to establish an upper bound on the size of $W$, we preliminarily need to show the following:

**Subclaim 1.** $W$ can be well-ordered.

*Proof.* Clearly, we can assume $W \in V_\eta$. Let $U \in W$. Then, by elementarity, $\pi(U)$ is a $\pi(V_\gamma)$-complete ultrafilter on $\pi(\delta^+)$, i.e., $\pi(U)$ is $V_{\pi(\gamma)}$-complete; so, since $U \in V_\gamma$ and $\pi(\gamma) > \eta$, we have that $\bigcap \pi^+ U \in \pi(U)$. Since $\bigcap \pi^+ U \subseteq \pi(\delta^+)$,
there exists the minimum of $\bigcap \pi^* U$; let $\nu_{U_0} = \min(\bigcap \pi^* U)$. Let us show that for $U_0, U_1 \in W$ such that $U_0 \neq U_1$, $\nu_{U_0} \neq \nu_{U_1}$. Since $U_0 \neq U_1$, there exists $X \subseteq \delta^+$ such that $X \in U_0$ and $\delta^+ \setminus X \in U_1$, so $\pi(X) \subseteq \pi(\delta^+)$ is such that $\pi(X) \in \pi(U_0)$ and $\pi(\delta^+ \setminus X) \in \pi(U_1)$. $\bigcap \pi^* U_0 \subseteq \pi(U_0)$ and $\bigcap \pi^* U_1 = \bigcap \{ \pi(Y) : Y \in U_0 \} \subseteq \pi(Y)$ for all $Y \in U_0$, hence $\bigcap \pi^* U_0 \subseteq \pi(X)$; similarly, $\bigcap \pi^* U_1 \subseteq \pi(\delta^+ \setminus X)$. So, since $\pi(X) \cap \pi(\delta^+ \setminus X) = \emptyset$, we have that $\bigcap \pi^* U_0 \cap \bigcap \pi^* U_1 = \emptyset$. Therefore, $\nu_{U_0} \neq \nu_{U_1}$, and so, $W$ can be well-ordered.

Since $W$ is a well-ordered family of ultrafilters, $W$ has a cardinality. Our next goal is to show the following:

**Subclaim 2.** $|W| < \delta_0$.

**Proof.** For contradiction, suppose that there exists a sequence $\langle W_\alpha : \alpha < \delta_0 \rangle$ of distinct elements of $W$. By the AC-Lemma, there exists a pair $\langle \mathbb{P}, \mathbf{e} \rangle \in V_\gamma$ such that $\mathbb{P}$ is cof($\delta$)-closed, $\delta_0 < \mathbf{e} < \gamma$, $\mathbf{e}$ is strongly inaccessible and $V^\mathbb{P} \models \mathbf{e}$-DC + “$\mathbf{e}$ is strongly inaccessible”. Let $G \subseteq \mathbb{P}$ be $V$-generic. Work in $V[G]$. First, let us show that in $V[G]$, each ultrafilter $W_\alpha$ generates a $V_\gamma$-complete ultrafilter. Let $T \subseteq \delta^+$, $T \in V[G]$, and fix a term $\tau \in \text{Name}_\mathbb{P}$ for $T$; let $p \in G$ be such that $p \Vdash \tau \subseteq \delta^+$. For all $q < p$, let $T_q = \{ \xi \in \delta^+ : q \Vdash \xi \in \tau \}$. It follows that $T = \bigcup \{ T_q : q < p \land q \in G \}$. Now, define $F : \{ q \in \mathbb{P} : q < p \} \rightarrow W_\alpha$ such that $F(q) = T_q$ if $T_q \in W_\alpha$ and $F(q) = \delta^+ \setminus T_q$ otherwise. Since the domain of $F$ is in $V_\beta$ for some $\beta < \gamma$ and $W_\alpha$ is $V_\gamma$-complete (in $V$), we have that $T^* = \bigcap F^* \text{dom}(F) \in W_\alpha$; moreover, notice that either $T^* \subseteq T$ or $T^* \subseteq \delta^+ \setminus T$, and so, either $T \in W_\alpha$ or $\delta^+ \setminus T \in W_\alpha$. Analogously, we can prove that the forcing doesn’t kill completeness. Let $\beta < \gamma$, $\rho : V_\beta \rightarrow W_\alpha$, $\rho \in V[G]$, and fix a term $\tau \in \text{Name}_\mathbb{P}$ for $\rho$; let $p \in G$ be such that $p \Vdash \tau$ is a function, $\text{dom}(\tau) = V_\beta$ and for all $x \in V_\beta$, $\tau(x) \in W_\alpha$. For all $q < p$, let $T_q = \{ X \in W_\alpha : \exists x \in V_\beta \ (q \Vdash \tau(x) = X) \}$. It
follows that $\rho^\mu V_\beta = \bigcup \{ T_q : q < p \land q \in G \} = \{ X \in W_\alpha : \exists q < p \ (q \in G \land X \in T_q) \} = \{ X \in W_\alpha : \exists q < p \ (q \in G \land \exists x \in V_\beta \ (q \Vdash \tau(x) = X)) \}$. Now, define $F : \{ q \in \mathbb{P} : q < p \} \times V_\beta \rightarrow W_\alpha$ such that $F((q, x)) = X$ iff $q \Vdash \tau(x) = X$. Since the domain of $F$ is in $V_\mu$ for some $\mu < \gamma$ and $W_\alpha$ is $V_\gamma$-complete (in $V$), we have that $T^* = \bigcap F^{\rightarrow \text{dom}(F)} \in W_\alpha$; but $T^* = \bigcap \{ X \in W_\alpha : \exists q < p \ \exists x \in V_\beta \ (q \Vdash \tau(x) = X) \} \subseteq \bigcap \rho^\mu V_\beta$, hence $\bigcap \rho^\mu V_\beta \in W_\alpha$. Therefore, in $V[G]$, for all $\alpha < \delta_0$, $W_\alpha$ generates a $V_\gamma$-complete ultrafilter. By $\varepsilon$-DC, in $V[G]$, there exists a sequence $\langle T_\alpha : \alpha < \delta_0 \rangle$ such that $T_\alpha \in W_\alpha$ for all $\alpha < \delta_0$ and $T_\alpha \cap T_\beta = \emptyset$ for all $\alpha, \beta < \delta_0$ such that $\alpha \neq \beta$ (i.e., there exists a separating family for $\langle W_\alpha : \alpha < \delta_0 \rangle$). It follows that there exists a sequence $\langle \hat{T}_\alpha : \alpha < \delta_0 \rangle \in V$ such that $\hat{T}_\alpha \in W_\alpha$ for all $\alpha < \delta_0$ and $\hat{T}_\alpha \cap \hat{T}_\beta = \emptyset$ for all $\alpha, \beta < \delta_0$ such that $\alpha \neq \beta$. Let us see why. In $V[G]$, let $F : \delta_0 \rightarrow \bigcup_{\alpha < \delta_0} W_\alpha$ be such that $F(\alpha) = T_\alpha \in W_\alpha$ for all $\alpha < \delta_0$ and $F(\alpha) \cap F(\beta) = \emptyset$ whenever $\alpha \neq \beta$. Let $\tau \in \text{Name}_\mu$ be a term for $F$ and choose $p \in G$ such that $p \Vdash \\tau$ is a function from $\delta_0$ into $\bigcup_{\alpha < \delta_0} W_\alpha$; $\tau(\alpha) \in W_\alpha$ for all $\alpha < \delta_0$ and $\tau(\alpha) \cap \tau(\beta) = \emptyset$ for all $\alpha, \beta < \delta_0$ such that $\alpha \neq \beta$. Now, for every $\alpha < \delta_0$, let $\hat{T}_\alpha = \bigcap \{ X \in W_\alpha : \exists q < p \ (q \Vdash \tau(\alpha) = X) \}$. Then, for each $\alpha < \delta_0$, by the completeness of $W_\alpha$, we have that $\hat{T}_\alpha \in W_\alpha$; moreover, since $\hat{T}_\alpha \subseteq T_\alpha$ for all $\alpha < \delta_0$, it is $\hat{T}_\alpha \cap \hat{T}_\beta = \emptyset$ for all $\alpha, \beta < \delta_0$ such that $\alpha \neq \beta$. Therefore, in $V$, there exists a separating sequence $\langle \hat{T}_\alpha : \alpha < \delta_0 \rangle$ for the sequence of ultrafilters $\langle W_\alpha : \alpha < \delta_0 \rangle$, where the separating sets $\hat{T}_\alpha$ are $\mathcal{F}_E$-positive. Since $\delta_0$ is a Berkeley cardinal, there exists $j : V_\mu \rightarrow V_\eta$ such that $\text{cof}(\delta) < \text{crit}(j) < \delta_0$, $j(\delta) = \delta$, $j(\delta_0) = \delta_0$, $j(\lambda) = \lambda$ and $j(\langle \hat{T}_\alpha : \alpha < \delta_0 \rangle) = \langle \hat{T}_{\alpha} : \alpha < \delta_0 \rangle$. It follows that $j \upharpoonright V_\delta : V_\delta \rightarrow V_{j(\delta)} = V_\delta$ is in $\mathcal{E}$, so $T = I_{j|_{V_\delta}} = \{ \alpha < \delta^+ : (\text{cof}(\alpha))^{L(V_{\delta+1})} = \lambda \land j(\alpha) = \alpha \} \in \mathcal{F}_E$. Now, let $\kappa_0 = \text{crit}(j) < \delta_0$. Since $T \in \mathcal{F}_E$ and $\hat{T}_{\kappa_0}$ is $\mathcal{F}_E$-positive, we have that $T \cap \hat{T}_{\kappa_0} \neq \emptyset$ (otherwise, $T \subseteq \delta^+ \setminus \hat{T}_{\kappa_0}$, hence $\delta^+ \setminus \hat{T}_{\kappa_0}$ would be in $\mathcal{F}_E$); so, choose $\alpha_0 \in T \cap \hat{T}_{\kappa_0}$. Then, by elementarity, $j(\alpha_0) \in \hat{T}_{j(\kappa_0)}$; but $j(\alpha_0) = \alpha_0$, so.
\[ \hat{T}_{\kappa_0} \cap \hat{T}_{\gamma_0} \neq \emptyset, \] a contradiction.

Now we know that the size of \( \mathcal{W} \) is less than \( \delta_0 \); so, let \( \mathcal{W} = \{ \mathcal{W}_\alpha : \alpha < \kappa_\mathcal{W} \} \)
where \( \kappa_\mathcal{W} = |\mathcal{W}| < \delta_0 \). Let \( \langle T_\alpha : \alpha < \kappa_\mathcal{W} \rangle \) be a separating family of \( \mathcal{F}_\mathcal{E} \)-positive sets for \( \mathcal{W} \) (we proved that there exists such a separating family). Notice that, for all \( \alpha < \kappa_\mathcal{W} \), \( T_\alpha \) cannot be split into \( \mathcal{F}_\mathcal{E} \)-positive sets. In fact: fix \( \alpha_0 < \kappa_\mathcal{W} \) and suppose for contradiction that \( T_{\alpha_0} \) can be split into \( \mathcal{F}_\mathcal{E} \)-positive sets, \( A, B \) (i.e., \( A \cup B = T_{\alpha_0} \) and \( A \cap B = \emptyset \)), and let \( \alpha_A \in \bigcap \pi^+(\mathcal{F}_\mathcal{E} \cap \pi(S) \cap \pi(A), \\alpha_B \in \bigcap \pi^+(\mathcal{F}_\mathcal{E} \cap \pi(S) \cap \pi(B)) \) (these sets are non-empty because \( \bigcap \pi^+(\mathcal{F}_\mathcal{E}), \pi(S) \in \pi(\mathcal{F}_\mathcal{E}) \) and \( \pi(A), \pi(B) \) are \( \pi(\mathcal{F}_\mathcal{E}) \)-positive); then, \( U_{\alpha_A} = \{ X \subseteq \delta^+ : \alpha_A \in \pi(X) \} \in \mathcal{W}, \ U_{\alpha_B} = \{ X \subseteq \delta^+ : \alpha_B \in \pi(X) \} \in \mathcal{W}, \ A \in U_{\alpha_A} \) and \( B \in U_{\alpha_B} \), but \( A, B \subseteq T_{\alpha_0} \), so \( T_{\alpha_0} \in U_{\alpha_A} \cap U_{\alpha_B} \), whence \( U_{\alpha_A} = U_{\alpha_B} = W_{\alpha_0} \), a contradiction.

It follows that for all \( \alpha < \kappa_\mathcal{W} \), \( \mathcal{F}_\mathcal{E} \upharpoonright T_\alpha \) is an ultrafilter: in fact, if \( Y \subseteq T_\alpha \) is such that \( Y \notin \mathcal{F}_\mathcal{E} \upharpoonright T_\alpha \) and \( T_\alpha \setminus Y \notin \mathcal{F}_\mathcal{E} \upharpoonright T_\alpha \), then \( Y \) and \( T_\alpha \setminus Y \) are both \( \mathcal{F}_\mathcal{E} \)-positive, and so, \( T_\alpha = Y \cup (T_\alpha \setminus Y) \) can be split into \( \mathcal{F}_\mathcal{E} \)-positive sets, a contradiction. But \( \mathcal{F}_\mathcal{E} \upharpoonright T_\alpha \subseteq \mathcal{W}_\alpha \upharpoonright T_\alpha \), and so, for all \( \alpha < \kappa_\mathcal{W} \), \( \mathcal{F}_\mathcal{E} \upharpoonright T_\alpha = \mathcal{W}_\alpha \upharpoonright T_\alpha \). Moreover, \( \bigcup_{\alpha < \kappa_\mathcal{W}} T_\alpha \in \mathcal{F}_\mathcal{E} \); in fact: every \( \mathcal{F}_\mathcal{E} \)-positive set is in some \( \mathcal{W}_\alpha \) (because for any \( \mathcal{F}_\mathcal{E} \)-positive set \( T \), since \( \bigcap \pi^+(\mathcal{F}_\mathcal{E}), \pi(S) \in \pi(\mathcal{F}_\mathcal{E}) \) and \( \pi(T) \) is \( \pi(\mathcal{F}_\mathcal{E}) \)-positive, there exists \( \alpha \in \bigcap \pi^+(\mathcal{F}_\mathcal{E} \cap \pi(S) \cap \pi(T)) \), and so, \( T \in \mathcal{W}_\alpha \)), so, \( \bigcap_{\alpha < \kappa_\mathcal{W}} \mathcal{W}_\alpha = \mathcal{F}_\mathcal{E} \).

Finally, we have shown that there exists a partition of \( S, \langle T_\alpha : \alpha < \kappa_\mathcal{W} \rangle \), into \( <\delta_0 \)-many \( \mathcal{F}_\mathcal{E} \)-positive sets such that for all \( \alpha < \kappa_\mathcal{W} \), \( \mathcal{F}_\mathcal{E} \upharpoonright T_\alpha \) is an ultrafilter.

We now turn to \( L(V_{\delta_1}) \). Recall that the filter \( \mathcal{F}_\mathcal{E} \) is correctly computed by \( L(V_{\delta_1}) \). Since \( \delta_0 \) is a limit of extendibles, we can choose an extendible \( \gamma \) such that \( \kappa_\mathcal{W} < \gamma < \delta_0 \). By the AC-Lemma, there exists a pair \( \langle \mathbb{P}, \epsilon \rangle \in V_\gamma \) such that \( \mathbb{P} \) is \( \text{cof}(\delta) \)-closed, \( \kappa_\mathcal{W} < \epsilon < \gamma \), \( \epsilon \) is strongly inaccessible and \( V^\mathbb{P} \models \epsilon-\text{DC} + \text{"\( \epsilon \) is strongly inaccessible"} \). Let \( G \subseteq \mathbb{P} \) be \( V \)-generic. Since \( V[G] \models \epsilon-\text{DC} \), we have that \( L(V_{\delta_1}[G]) = L(V_{\delta_1})[G] \models \epsilon-\text{DC} \) (notice that
4.4. MEASURABILITY OF $\delta^+$

$L(V_{\delta+1}[G]) = L(V_{\delta+1})[G]$ follows from the fact that $\mathbb{P}$ is cof($\delta$)-closed. Let us show the following:

**Claim 3.**

1. If $T \subseteq S$ is $\mathcal{F}_\mathcal{E}$-positive in $L(V_{\delta+1})[G]$, then $T$ contains an $\mathcal{F}_\mathcal{E}$-positive subset in $L(V_{\delta+1})$.

2. In $L(V_{\delta+1})[G]$, there is no partition of $S$ into $\epsilon$-many $\mathcal{F}_\mathcal{E}$-positive sets.

**Proof.**

1. Let $\tau \in \text{Name}_\mathbb{P}$ be a term for $T$, $\tau \in L(V_{\delta+1})$. Choose $p \in G$ such that $p \models \text{“$\tau$ is an $\mathcal{F}_\mathcal{E}$-positive subset of $S$”}$. For all $q < p$, let $T_q = \{\xi \in S : q \models \xi \in \tau\}$. Then, $T = \bigcup\{T_q : q < p \wedge q \in G\}$. So, in $L(V_{\delta+1})[G]$, $T \subseteq S$ is $\mathcal{F}_\mathcal{E}$-positive and $T$ is the union of sets of the ground model; it follows that some set $T_q$ has to be $\mathcal{F}_\mathcal{E}$-positive: in fact, if not, $S \setminus T_q \in \mathcal{F}_\mathcal{E}$ for each $q$, but then, since $\mathcal{F}_\mathcal{E}$ is $V_{\delta}[G]$-complete in $L(V_{\delta+1})[G]$, $\bigcap\{S \setminus T_q : q < p \wedge q \in G\} = S \setminus \bigcup\{T_q : q < p \wedge q \in G\} = S \setminus T \in \mathcal{F}_\mathcal{E}$, a contradiction.

2. Suppose for contradiction that $\langle S_\beta : \beta < \epsilon \rangle \in L(V_{\delta+1})[G]$ is a partition of $S$ into $\epsilon$-many $\mathcal{F}_\mathcal{E}$-positive sets. We have that each set $S_\beta$ contains an $\mathcal{F}_\mathcal{E}$-positive subset $\bar{S}_\beta$ in the ground model. Then, each set $\bar{S}_\beta$ has to be in some $\mathcal{W}_\alpha$ (in fact, every $\mathcal{F}_\mathcal{E}$-positive set of $V$ is in some $\mathcal{W}_\alpha$). Thus, in $V[G]$, each set $S_\beta$ is in some $\mathcal{W}_\alpha$ (recall that each $\mathcal{W}_\alpha$ generates a $V_\gamma$-complete ultrafilter in $V[G]$); but each $\mathcal{W}_\alpha$ can contain a unique $S_\beta$ (as the sets $S_\beta$ are pairwise disjoint), and so, it follows that $|\kappa_{\mathcal{W}}|^{|V[G]|} \geq |\epsilon|^{|V[G]|}$ (i.e., in $V[G]$, there exists $\rho : \kappa_{\mathcal{W}} \overset{onto}{\rightarrow} \epsilon$), contradicting $|\kappa_{\mathcal{W}}|^{|V[G]|} \leq \kappa_{\mathcal{W}} < \epsilon = |\epsilon|^{|V[G]|}$.

Since $\delta^+$ is regular, we have that the filter $\mathcal{F}_\mathcal{E}$ is $\delta^+$-complete. It follows that in $L(V_{\delta+1})[G]$, there exist a cardinal $\sigma < \epsilon$ and a partition $\langle S_\alpha : \alpha < \sigma \rangle$ of
4.4. MEASURABILITY OF $\delta^+$

$S$ into $\mathcal{F}_\mathcal{E}$-positive sets on each of which $\mathcal{F}_\mathcal{E}$ is an ultrafilter; in fact: by $\epsilon$-DC and since $\mathcal{F}_\mathcal{E}$ is $\delta^+$-complete, we have that in $L(V_{\delta+1})[G]$, either

1. there exists a partition of $S$ into $\prec \epsilon$-many $\mathcal{F}_\mathcal{E}$-positive sets on each of which $\mathcal{F}_\mathcal{E}$ is an ultrafilter

or

2. there exists a partition of $S$ into $\epsilon$-many $\mathcal{F}_\mathcal{E}$-positive sets;

but we have shown that the second case cannot happen. Since for each $\alpha < \sigma$, $S_\alpha$ contains an $\mathcal{F}_\mathcal{E}$-positive subset $\hat{S}_\alpha$ in the ground model and $S_\alpha$ cannot be split into $\mathcal{F}_\mathcal{E}$-positive sets, we have that for each $\alpha < \sigma$, $\hat{S}_\alpha$ cannot be split into $\mathcal{F}_\mathcal{E}$-positive sets in the ground model. Therefore, we can assume that $S_\alpha \in L(V_{\delta+1})$ for all $\alpha < \sigma$. So, in $L(V_{\delta+1})$, $\mathcal{F}_\mathcal{E} \upharpoonright S_\alpha$ is an ultrafilter for all $\alpha < \sigma$. Now we need a well-ordering of these ultrafilters. Let us define, in $V$, an equivalence relation on $\mathcal{W} = \{U_\alpha : \alpha \in \cap \pi^{\mathcal{F}_\mathcal{E}} \cap \pi(S)\} = \langle W_\alpha : \alpha < \kappa_\mathcal{W}\rangle$ (where $\kappa_\mathcal{W} = |\mathcal{W}|^{V} < \delta_0$) as follows: for $U_1, U_2 \in \mathcal{W}$, $U_1 \sim U_2$ iff $U_1 \cap L(V_{\delta+1}) = U_2 \cap L(V_{\delta+1})$. First, we show that for all $U \in \mathcal{W}$, $U \cap L(V_{\delta+1}) \in L(V_{\delta+1})$. Let $\langle T_\alpha : \alpha < \kappa_\mathcal{W}\rangle$ be a separating family of $\mathcal{F}_\mathcal{E}$-positive sets for $\mathcal{W}$ (so, $T_\alpha \in \mathcal{W}_{\alpha}$ for all $\alpha < \kappa_\mathcal{W}$, $T_\alpha \cap T_\beta = \emptyset$ for all $\alpha \neq \beta$, $\bigcup_{\alpha < \kappa_\mathcal{W}} T_\alpha = S$ and each $T_\alpha$ cannot be split into $\mathcal{F}_\mathcal{E}$-positive sets), and let $\bar{\alpha} < \sigma$; since $S_{\bar{\alpha}} = \bigcup\{S_\alpha \cap T_\alpha : \alpha < \kappa_\mathcal{W}\}$ is $\mathcal{F}_\mathcal{E}$-positive, there must exist $\alpha^* < \kappa_\mathcal{W}$ such that $S_\alpha \cap T_{\alpha^*}$ is $\mathcal{F}_\mathcal{E}$-positive, but $T_{\alpha^*}$ cannot be split into $\mathcal{F}_\mathcal{E}$-positive sets, so $W_{\alpha^*} \cap L(V_{\delta+1}) = (\mathcal{F}_\mathcal{E} \upharpoonright S_\alpha)^{L(V_{\delta+1})} \in L(V_{\delta+1})$. Now, let $\mathcal{W}^* = \{U \cap L(V_{\delta+1}) : U \in \mathcal{W}\}$. Then, $\mathcal{W}^* \in L(V_{\delta+1})$, as $\mathcal{W}^* = \{(\mathcal{F}_\mathcal{E} \upharpoonright T)^{L(V_{\delta+1})} : T \in L(V_{\delta+1}) \land \text{"T is } \mathcal{F}_\mathcal{E}\text{-positive and cannot be split"} \} = \{(\mathcal{F}_\mathcal{E} \upharpoonright S_\alpha)^{L(V_{\delta+1})} : \alpha < \sigma\}$. Moreover:

**Claim 4.** In $L(V_{\delta+1})$, $\mathcal{W}^*$ can be well-ordered.

**Proof.** First, notice that $\mathcal{W}^*$ can be well-ordered in $V$, as there exists $\rho^* : \mathcal{W} \longrightarrow \mathcal{W}^*$ and $\mathcal{W}$ can be well-ordered. Thus, $|\mathcal{W}^*|^{V} \leq |\mathcal{W}|^{V} = \kappa_\mathcal{W}$. Fix
4.4. MEASURABILITY OF $\delta^+$

a bijection $\rho : |\mathcal{W}^*|^{V} \leftrightarrow \mathcal{W}^*$. Let us show that $\rho \in L(V_{\delta+1})$. Since $|\mathcal{W}^*|^{V} \leq \kappa_W$, $|\mathcal{W}^*|^{V[G]} \leq \kappa_W < \epsilon$; since $\mathcal{W}^* \in L(V_{\delta+1})(G)$ and $L(V_{\delta+1})[G] \models \epsilon$-DC, it follows that $\mathcal{W}^*$ can be well-ordered in $L(V_{\delta+1})(G)$ and $|\mathcal{W}^*|^{L(V_{\delta+1})[G]} < \epsilon$. So, $(\mathcal{P}(\mathcal{W}^* \times \mathcal{W}^*))^{V[G]} = (\mathcal{P}(\mathcal{W}^* \times \mathcal{W}^*))^{L(V_{\delta+1})[G]}$ and, thus, $\rho \in L(V_{\delta+1})$; but $G$ is $\mathcal{V}$-generic, hence $\rho \in L(V_{\delta+1})$. Therefore, $\mathcal{W}^*$ is well-ordered in $L(V_{\delta+1})$ and $|\mathcal{W}^*|^{L(V_{\delta+1})} = |\mathcal{W}^*|^{V}$.

Finally, since $\mathcal{W}^*$ is well-ordered in $L(V_{\delta+1})$ and $|\mathcal{W}^*|^{L(V_{\delta+1})} = |\mathcal{W}^*|^{V} \leq \kappa_W < \delta_0$, we can get a separating family for $\mathcal{W}^*$ and conclude that in $L(V_{\delta+1})$ there exists a partition of $S$ into $<\delta_0$-many $\mathcal{F}_\mathcal{E}$-positive sets on each of which the filter $\mathcal{F}_\mathcal{E}$ is an ultrafilter. Since $\mathcal{F}_\mathcal{E}$ is $\delta^+$-complete, we are done.

The following theorem generalizes the splitting result achieved in the proof of Theorem 4.4.1 by considering in place of $\delta^+$ any cardinal $\kappa > \delta$ such that $\kappa < \Theta$ and $\text{cof}(\kappa) > \delta$: it turns out that, unlike the $\text{I}_0$ case, here we get a uniform bound ($\delta_0$, that can be the least Berkeley cardinal which is limit of extendibles) independent of the cofinality.

**Theorem 4.4.2.** Assume $T^*$. Let $\delta_0$ be a Berkeley cardinal and a limit of extendibles such that $\text{cof}(\delta) < \delta_0 < \delta$. Then in $L(V_{\delta+1})$, for any cardinal $\kappa < \Theta$ such that $\text{cof}(\kappa) > \delta$ and for any infinite regular cardinal $\lambda < \kappa$, there exists a partition of $S^*_\kappa = \{ \alpha < \kappa : (\text{cof}(\alpha))^{L(V_{\delta+1})} = \lambda \}$ into $<\delta_0$-many $\mathcal{F}_\mathcal{E}$-positive sets on each of which the filter $\mathcal{F}_\mathcal{E}$ is an ultrafilter, where $\mathcal{F}_\mathcal{E}$ is the “fixed points filter”.

**Proof.** We just need to define the general setting in which performing the proof of Theorem 4.4.1. So, let $\kappa < \Theta$ be such that $\text{cof}(\kappa) > \delta$ and let $\lambda < \kappa$ be such that $\lambda$ is regular in $L(V_{\delta+1})$. Let $\beta < \Theta$ be such that $(\mathcal{P}(\kappa))^{L(V_{\delta+1})} \subseteq L_\beta(V_{\delta+1})$.

Then, let $\mathcal{E}_{\kappa, \lambda, \beta}^\delta = \mathcal{E} = \{ j : L_\beta(V_{\delta+1}) \to L_\beta(V_{\delta+1}) : \text{cof}(\delta) < \text{crit}(j) < \delta_0 \land j(\delta) = \delta \land j(\delta_0) = \delta_0 \land j(\kappa) = \kappa \land j(\lambda) = \lambda \land j(\beta) = \beta \}$. Notice that, for all $j \in \mathcal{E}$, $j$ is uniquely determined by $j \upharpoonright V_\delta$. For any $\mathcal{X} \subseteq \mathcal{E}$ such that there exists
4.5. MEASURABLE CARDINALS UP TO $\Theta$

We finally prove that in $L(V_{\delta+1})$, $\Theta$ is a limit of measurable cardinals. We preliminarily note that the proof of the Coding Lemma works locally in any $L_\gamma(V_{\delta+1})$ with $\gamma < \Theta$ such that $\text{cof}(\gamma) > \delta$. Therefore, we have the following local version of the Coding Lemma.

**Lemma 4.5.1** (Local version of the Coding Lemma). Assume $T^*$. Let $\gamma < \Theta$ be such that $\text{cof}(\gamma) > \delta$. Then, the Coding Lemma holds in $L_\gamma(V_{\delta+1})$.

**Theorem 4.5.2.** Assume $T^*$. Then in $L(V_{\delta+1})$, $\Theta$ is limit of measurable cardinals.

**Proof.** Work in $L(V_{\delta+1})$. Let us show the following:

**Claim.** Let $\gamma < \Theta$ be the least such that $L_\gamma(V_{\delta+1}) \prec L_{\Theta}(V_{\delta+1})$. Then in $L(V_{\delta+1})$, $\gamma$ is measurable.

**Proof.** Let $\delta_0 < \delta$ be such that $\delta_0 > \text{cof}(\delta)$ is a Berkeley cardinal and a limit of extendibles. Let $\lambda < \gamma$ be an infinite regular cardinal such that $\lambda$ is regular in $L(V_{\delta+1})$. Let $S^\gamma_\lambda = S = \{\alpha < \gamma : (\text{cof}(\alpha))^{L(V_{\delta+1})} = \lambda\}$. Let $\mathcal{E} = \{j : L_\gamma(V_{\delta+1}) \rightarrow L_\gamma(V_{\delta+1}) : \text{cof}(\delta) < \text{crit}(j) < \delta_0 \wedge j(\delta) = \delta \wedge j(\delta_0) = \delta_0 \wedge j(\gamma) = \gamma \wedge j(\lambda) = \lambda\}$. For any $\mathcal{X} \subseteq \mathcal{E}$ such that there exists $\pi : V_\delta \overset{\text{onto}}{\rightarrow} X$, let $I_\mathcal{X} = \{\alpha < \gamma : (\text{cof}(\alpha))^{L(V_{\delta+1})} = \lambda \wedge (j(\alpha) = \alpha \forall j \in \mathcal{X})\}$. Let $F_\mathcal{E}$ be the filter generated by $\{I_\mathcal{X} : \mathcal{X} \subseteq \mathcal{E} \wedge \exists \pi : V_\delta \overset{\text{onto}}{\rightarrow} \mathcal{X}\}$, that is, let $F_\mathcal{E} = \{X \subseteq \gamma : \exists \mathcal{X} \subseteq \mathcal{E} (\exists \pi : V_\delta \overset{\text{onto}}{\rightarrow} \mathcal{X} \wedge I_\mathcal{X} \subseteq X)\}$. We claim that $F_\mathcal{E}$ is $\gamma$-complete. Fix a surjection $\pi : \text{dom}(\pi) \overset{\text{onto}}{\rightarrow} L_\gamma(V_{\delta+1})$ such that $\text{dom}(\pi) \subseteq V_{\delta+1}$, $\pi$ is
Then, for all $j$ let $\alpha$ be witness of the Coding Lemma at $j$. So, we let $f_{\gamma}(\alpha) = \alpha$ be such that $I_{\gamma} \subseteq f(\alpha)$ such that $\alpha$ is $\Sigma_1$-definable from $\{V_{\delta+1}\}$ in $L_{\gamma}(V_{\delta+1})$. Notice that, for all $j$ such that $I_{\gamma} \subseteq f(\alpha)$, $\alpha$ is uniquely determined by its action on $V_{\delta}$ (i.e., for all $j_1, j_2 \in E$, if $j_1 \mid V_{\delta} = j_2 \mid V_{\delta}$ then $j_1 = j_2$), and so there exists a canonical bijection between $E$ and $E^*$. Let $\alpha < \gamma$ and $f : \alpha \to F$; we have to show that $\bigcap f^{-1}(\alpha) \in F_E$. Since $\text{cof}(\gamma) > \delta$, the Coding Lemma holds in $L_{\gamma}(V_{\delta+1})$; so, we can let $\beta < \gamma$ be such that $L_{\beta}(V_{\delta+1})$ witnesses the Coding Lemma at $\alpha$ in $L_{\gamma}(V_{\delta+1})$ (notice that, since $L_{\gamma}(V_{\delta+1}) \prec \Sigma_1 L_{\alpha}(V_{\delta+1})$, $L_{\beta}(V_{\delta+1})$ turns to be witness of the Coding Lemma at $\alpha$ in $L_{\alpha}(V_{\delta+1})$). Choose $\rho : V_{\delta+1} \to E$ such that $\rho(\alpha) = \alpha$, $\rho \in L_{\gamma}(V_{\delta+1})$. Let $W = \{ (x,y) : y : V_{\delta} \to E^* \wedge \text{"}y\text{"} \text{ gives a set } \hat{X} \subseteq E \text{ such that } I_{\hat{X}} \subseteq f(\rho(x)) \} \subseteq V_{\delta+1} \times V_{\delta+1}$, where we mean that $\hat{X}$ contains the extension to $L_{\gamma}(V_{\delta+1})$ of every element of $y \restriction V_{\delta}$ (recall that every element of $E^*$ extends uniquely to an element of $E$). By the Coding Lemma, there exists $W^* \in L_{\beta}(V_{\delta+1})$ such that $W^* \subseteq W$ and for all $\xi < \alpha$, if there exists $(x,y) \in W^*$ such that $\rho(x) = \xi$ then there exists $(x,y) \in W^*$ such that $\rho(x) = \xi$. Now, let $E^*_0 = \bigcup \{ y : V_{\delta+1} \subseteq E \} \subseteq W^*$ such that $\rho(x) = \xi$. Since for all $(x,y) \in W^*$, $y \restriction V_{\delta} \subseteq E^*$, we have that $E^*_0 \subseteq E^*$; moreover, since $E^*_0$ is definable from $W^*$ and $W^* \in L_{\beta}(V_{\delta+1})$, $E^*_0 \in L_{\beta+1}(V_{\delta+1}) \subseteq L_{\gamma}(V_{\delta+1})$. In order to prove that $F_E$ is $\gamma$-complete, it suffices to show that $\bigcap f^{-1}(\alpha) \neq \emptyset$. We preliminarily show the following:

**Subclaim.** Suppose $Z \subseteq E^*$, $Z \in L_{\gamma}(V_{\delta+1})$. Then, $\{ \eta < \gamma : \forall j \in E \ (j \mid V_{\delta} \in Z \to j(\eta) = \eta) \}$ is cofinal in $\gamma$.

**Proof.** Let $\eta < \gamma$ and let $a \in \text{dom}(\pi)$ be such that $\pi(a) = \eta$. Let $Y = \{ j(a) : j \in E \wedge j \mid V_{\delta} \in Z \}$. Then, $Y \subseteq \text{dom}(\pi)$ (as for all $j \in E$, $j(\pi) = \pi$, so $j(a) \in j(\text{dom}(\pi)) = \text{dom}(j(\pi)) = \text{dom}(\pi)$) and $Y \in L_{\gamma}(V_{\delta+1})$. It follows
that $\pi \upharpoonright Y \in L_\gamma(V_{\delta+1})$; thus, $\sup\{j(\eta) : j \in \mathcal{E} \wedge j \upharpoonright V_\delta \in \mathcal{Z}\} < \gamma$: in fact, $\sup\{j(\eta) : j \in \mathcal{E} \wedge j \upharpoonright V_\delta \in \mathcal{Z}\} = \sup\{j(\pi(a)) : j \in \mathcal{E} \wedge j \upharpoonright V_\delta \in \mathcal{Z}\} = \sup\{j(\pi)(j(a)) : j \in \mathcal{E} \wedge j \upharpoonright V_\delta \in \mathcal{Z}\} = \sup\{\pi(a) : j \in \mathcal{E} \wedge j \upharpoonright V_\delta \in \mathcal{Z}\} = sup \pi "Y$. So, since $\sup\{j(\eta) : j \in \mathcal{E} \wedge j \upharpoonright V_\delta \in \mathcal{Z}\} < \gamma$ for any $\eta < \gamma$, the set $\{\eta < \gamma : \forall j \in \mathcal{E} (j \upharpoonright V_\delta \in \mathcal{Z} \rightarrow j(\eta) = \eta)\}$ must be cofinal in $\gamma$. □

So, we have that the set $\{\eta < \gamma : \forall j \in \mathcal{E} (j \upharpoonright V_\delta \in \mathcal{E}_0^* \rightarrow j(\eta) = \eta)\}$ is cofinal in $\gamma$. It follows that there exists $\eta < \gamma$ such that $\eta \in S$ and $j(\eta) = \eta$ for all $j \in \mathcal{E}$ such that $j \upharpoonright V_\delta \in \mathcal{E}_0^*$ (since $S$ is stationary and $\{\eta < \gamma : \forall j \in \mathcal{E} (j \upharpoonright V_\delta \in \mathcal{E}_0^* \rightarrow j(\eta) = \eta)\}$ is club in $\gamma$). Then, for all $\langle x, y \rangle \in W^*$, $\eta \in f(\rho(x))$: in fact, $\eta$ is fixed by any embedding in $y"V_\delta$, each of which extends to an embedding in $\hat{\mathcal{X}} \subseteq \mathcal{E}$ such that $I_{\hat{\mathcal{X}}} = \{\alpha < \gamma : (\text{cof}(\alpha))^{L(V_{\delta+1})} = \lambda \wedge (j(\alpha) = \alpha \forall j \in \hat{\mathcal{X}})\} \subseteq f(\rho(x))$. Now, notice that for all $\xi < \alpha$ there exists $\langle x, y \rangle \in W$ such that $\rho(x) = \xi$; in fact: for every $\xi < \alpha$ there exists $x \in V_{\delta+1}$ such that $\rho(x) = \xi$, so $f(\rho(x)) = f(\xi) \in \mathcal{F}_\mathcal{E}$; that is, there exists a “small” $\hat{\mathcal{X}} \subseteq \mathcal{E}$ such that $I_{\hat{\mathcal{X}}} \subseteq f(\rho(x))$, and so, if we let $y : V_\delta \rightarrow \mathcal{E}^*$ be such that $y"V_\delta = \{j \upharpoonright V_\delta : j \in \hat{\mathcal{X}}\} \subseteq \mathcal{E}^*$, then $\langle x, y \rangle \in W$. Therefore, for all $\xi < \alpha$ there exists $\langle x, y \rangle \in W^*$ such that $\rho(x) = \xi$. It follows that for all $\xi < \alpha$, $\eta \in f(\xi)$, i.e., $\eta \in \bigcap f "\alpha$, and so, $\bigcap f "\alpha \neq \emptyset$ and $\mathcal{F}_\mathcal{E}$ is $\gamma$-complete. Finally, by Theorem 4.4.2, we have that in $L(V_{\delta+1})$ there exists a partition of $S$ into $<\delta_0$-many $\mathcal{F}_\mathcal{E}$-positive sets on each of which $\mathcal{F}_\mathcal{E}$ is an ultrafilter. Since $\mathcal{F}_\mathcal{E}$ is $\gamma$-complete, we are done. □

The same argument applies to show that if we fix $\beta < \Theta$ and let $\gamma_\beta$ be the least such that $\gamma_\beta > \beta$ and $L_{\gamma_\beta}(V_{\delta+1}) \prec \Sigma_1 L_{\Theta}(V_{\delta+1})$, then in $L(V_{\delta+1})$, $\gamma_\beta$ is measurable. So, the proof is complete. □
Chapter 5

Conclusion

The large cardinal axioms investigated in this dissertation have been introduced in [1] with two major purposes:

1. that of finding a deep inconsistency

and

2. that of showing they can provide a rich mathematical structure.

In the first aim we noted that the inconsistency of Berkeley cardinals with ZF would actually follow by the HOD Conjecture; in the second aim we explored how choiceless large cardinals affect the structure theory of a remarkable model of ZF. Moreover, we proved that the cofinality of the least Berkeley cardinal is undecidable, and this is concerned with the main feature of Berkeley cardinals: they contradict AC. In this regard, one may observe that the evidence for AC is so compelling, that it would seem somewhat unlikely to drop AC (or even just part of AC) by the motivation that the large cardinal hierarchy can be extended beyond the “upper bound” established by Kunen’s theorem in the context of ZFC. But the question here is more subtle...
5.1. TWO FUTURES

There is a really basic issue involved in the conflict between very large cardinals and AC: it is the search for “V”, i.e., the ultimate purpose of discovering the “right” axiom for a definitive description of the universe of set theory. Of course, this would also settle the fundamental question of which strong axioms of infinity must be regarded as true. Our final comments are devoted to outline the recent progress made in this direction, as choiceless large cardinals could actually play a crucial role in the resulting scenario.

5.1 Two futures

The justification of the consistency of a large cardinal axiom in set theory is arguably provided through the determination of the smallest inner model satisfying it; this investigation is the object of inner model theory and results in the construction of enlargements of the constructible universe $L$. The real question in seeking the proper axiom for $V$ turns in fact to be the following:

Could there be an ultimate version of Gödel’s $L$?

Woodin’s Ultimate-$L$ Conjecture surmises a positive answer to this question; even a candidate for the final axiom for $V$, “$V = $ Ultimate-$L$”, has been formulated by Woodin. A suitable understanding of the axiom “$V = $ Ultimate-$L$” requires much additional material from [6] and [7]; however, some preliminary remarks will allow us to give the statement of the Ultimate-$L$ Conjecture and display its implications.

The following results established by Woodin in [6] are exposed here as revisited in [5].

Theorem 5.1.1 (HOD Dichotomy). Suppose $\delta$ is an extendible cardinal. Then exactly one of the following holds.
1. For every singular cardinal $\gamma > \delta$, $\gamma$ is singular in $\text{HOD}$ and $(\gamma^+)_{\text{HOD}} = \gamma^+$ (i.e., $\text{HOD}$ is close to $V$).

2. Every regular cardinal greater than $\delta$ is measurable in $\text{HOD}$ (i.e., $\text{HOD}$ is far from $V$).

**Theorem 5.1.2.** The following statement is absolute between $V$ and its generic extensions by partial orders in $V_\delta$: “$\delta$ is an extendible cardinal and for every singular cardinal $\gamma > \delta$, $\gamma$ is singular in $\text{HOD}$ and $(\gamma^+)_{\text{HOD}} = \gamma^+$”.

**Definition 5.1.3.** A transitive class model $N$ of ZFC is a weak extender model for $\delta$ supercompact iff for every $\gamma > \delta$ there exists a normal fine measure $\mathcal{U}$ on $\mathcal{P}_\delta(\gamma) = \{X \subseteq \gamma : |X| < \delta\}$ such that

1. $N \cap \mathcal{P}_\delta(\gamma) \in \mathcal{U}$ (i.e., $\mathcal{U}$ concentrates on $N$) and

2. $\mathcal{U} \cap N \in N$ (i.e., $\mathcal{U}$ is amenable to $N$).

**Theorem 5.1.4.** Suppose $\delta$ is an extendible cardinal. Then the following are equivalent.

1. The HOD Conjecture.

2. HOD is a weak extender model for $\delta$ supercompact.

3. For every singular cardinal $\gamma > \delta$, $\gamma$ is singular in HOD and $(\gamma^+)_{\text{HOD}} = \gamma^+$.

**Theorem 5.1.5 (Universality).** Suppose $\delta$ is an extendible cardinal, $N$ is a weak extender model for $\delta$ supercompact and $\gamma > \delta$. Let $j : N \cap V_{\gamma+1} \rightarrow N \cap V_{j(\gamma)+1}$ be a non-trivial elementary embedding with $\text{crit}(j) \geq \delta$. Then, $j \in N$.

Theorem 5.1.5 says that if $\delta$ is an extendible cardinal and $N$ is a weak extender model for $\delta$ supercompact, then $N$ sees all elementary embeddings between its levels; this implies a sort of analogue of Kunen’s theorem for $N$.
Theorem 5.1.6. Suppose \( \delta \) is an extendible cardinal and \( N \) is a weak extender model for \( \delta \) supercompact. Then there is no non-trivial elementary embedding \( j : N \to N \) with \( \text{crit}(j) \geq \delta \).

Proof. Suppose for contradiction that there exists a non-trivial elementary embedding \( j : N \to N \) with \( \text{crit}(j) \geq \delta \). Let \( \kappa > \text{crit}(j) \geq \delta \) be a fixed point of \( j \). Then, \( i = j \upharpoonright (V_{\kappa+2})^N : (V_{\kappa+2})^N \to (V_{\kappa+2})^N \) is a non-trivial elementary embedding with \( \text{crit}(i) = \text{crit}(j) \geq \delta \); by Theorem 5.1.5, \( i \in N \), contradicting the local version of Kunen’s Theorem within \( N \).\(^1\)

Corollary 5.1.7. Assume the HOD Conjecture. If \( \delta \) is an extendible cardinal, then there is no non-trivial elementary embedding \( j : \text{HOD} \to \text{HOD} \) with \( \text{crit}(j) \geq \delta \).

Notice that by “universality”, a weak extender model is capable to recognize all large cardinals (below the Kunen inconsistency), accomplishing this way the idea of being “close to \( V \)”; under the HOD Conjecture, this property is satisfied by HOD itself. We now state the Ultimate-\( L \) Conjecture, which will complete the picture.

Ultimate-\( L \) Conjecture. Suppose \( \delta \) is an extendible cardinal. Then there exists a weak extender model for \( \delta \) supercompact \( N \) such that:

1. \( N \subseteq \text{HOD} \).

2. \( N \models \text{“} V = \text{Ultimate-} L \text{”} \).

Theorem 5.1.8. Assume \( \text{ZF + “} V = \text{Ultimate-} L \text{”} \). Then the following hold.

1. \( V = \text{HOD} \).

2. \( \text{AC} \).

\(^1\)Recall that the local version of Kunen’s theorem states that for any \( \kappa \), there is no non-trivial elementary embedding \( j : V_{\kappa+2} \to V_{\kappa+2} \).
3. CH.²

At this point, the perspective emerges clearly: there are two plausible futures for the development of set theory, each of which leading to a real turning point in the subject.

The prospect displayed above is significative in bringing together the search for deep inconsistency and the search for \( V \): so finally, the study of choiceless large cardinal axioms is possibly the key for a further, and maybe decisive, understanding of \( V \).

²The Continuum Hypothesis (CH) is the statement that \( 2^{\aleph_0} = \aleph_1 \).
